Haven't tried to build it yet, just kicking around the idea since I
have the aluminum and not the fiberglass.

Roy

All comments noted. I do in fact live within 2km of an AM transmitter
although I believe it's not that high powered and I also have an FM
transmitter within 5km, therefore I'm interested in the details of your
location in relation to the various transmitters.

I live in a very rural area and mine works as advertised.

I don't use it very much because it gives quick and complete answers.

Peter,

Effective exploitation of the capability of this type of analyser depends on a sound understanding of transmission lines, and of the instrument's own limitation. The availability of these analysers at low cost, and the perception that they are a magic bullet has lead to a lot of pseudo technical nonsense being proposed. The magic is more in the user's capability than the box, and buying the box doesn't buy knowledge and understanding... but the device can help develop knowledge and understanding.

I have not used a '269 (though I have extensively used a '259B), but I suspect that it does not display the sign of X. Estimation of the sign of X in the '259 and similar instruments is an issue, and confuses many users. There are propositions that sign of X is easily determined from the slope of X with frequency at a point... but whilst that is true for an ideal passive component, it is not true in general.

These instruments are often used in pursuit of the questionable goal of resonance, and the instrument used to show resonance by observing X=0, or X approximately zero, or a local minimum for X at some frequency on the assumption that X changes sign at that point and that resonance of something is indicated.

I wrote some notes entitled "In pursuit of dipole resonance with an MFJ259B" at http://vk1od.net/blog/?p=680 that canvasses the behaviour of the instrument in such an application, and flags the issues in measurement. You may find them interesting.

Others have raised the issue that these instruments use a broadband detector, which works fine so long as the internal oscillator has low harmonic content and dominates the detector. If you let one of these things time out, the oscillator is shut down, and if you see indication on the meters, then energy from another source is of sufficient magnitude to be concerned about the accuracy of measurements.

Hi Jimmie

Some years ago I made a 3 el 10M quad that was actually a bow tie arrangement. ie the spreaders were "driven" and the side "elements" were rope.

Probably not what you are thinking about but it did look like a 3 el 20m quad! I should have modeled it in later years but never got around to it. It worked okay at the time but I wasnt exactly doing any extensive testing.

Does modeling the metal spreaders give you any ideas?

Cheers Bob

Roughly 10 - 15 miles from here is a ridge about 800 feet higher than my location. On top are virtually all the TV and FM, and a number of the AM, transmitters for the Portland Oregon metropolitan area. A single strong transmitter is likely to be enough to confuse an antenna analyzer, though. Filtering is possible, of course, but you have to take care to design filters to have minimal effect on measured impedances while still filtering effectively. This can sometimes be challenging depending on the strength of the interfering signal and how far it is from the measurement frequency.

I also have to be careful when working on audio circuitry -- on several occasions I've tracked down "hum" as demodulated TV video, and I end up having to include VHF decoupling and shielding to audio circuits. Don't know much about the nature of HDTV signals, but it might not be so bad if it doesn't have as much energy in the AF range when demodulated. It's bound to drive untuned antenna analyzers bonkers, though.

I have put together a HyGain 2 element quad that used aluminum spreaders and it worked fine. Like you indicated you do have to keep the elements insulated from the spreaders. Spreaders made of fiberglass or plastic pipe work great too. Rollie

Hi Peter,

I can highly recommend the Rigexpert AA-200A:
http://www.rigexpert.com/index?s=aa200

Unlike the MFJ unit, this is a full vector analyzer. You can also save plots and then transfer them to your computer for archiving. The lates firmware allows measurements at both 50 Ohms and 75 Ohms and I believe one can now also move the reference plane to the end of the coax. Batteries last forever, it's about 1/4th the weight, can display data in both graphical and tabular format.
I've owned the MFJ, Autek, AEA and Timewave- the AA-200A blows them all away. Oh yeah, the signal source is synthesized and can make a very nice signal generator that is rock stable.

Dale W4OP

They're a little expensive, but well worth the money. It's easy to set up a factory made antenna with and a blessing when building homemade antennas. The analyzer leaves nothing to guess about as it's all read out. I haven't used it yet, but it also has a frequency counter input. That's just another use that make the MFJ-269 indispensable. Rollie

> frequency) get some interesting result.

I once read an article in which it was stated that in a simple vertical, the element current it restricted by the ground current, and any attempt to increase the ground curent resulted in an increase in efficiency. The article went on to state that an antenna having maximum contact with the ground would be the most efficient, and in test a 1/2-wave dipole burried underground could have an efficiency approaching 98% that of a dummy load. The advantages are numerouse, such as the lack of an antenna support structure, but for VHF arrays there could be a huge problem with direction since the torque required to turn only a 2m 8-ele Yagi would be over a ton.

Except that it looks like the RigExpert has an untuned detector, just
like the others. The schematic SUBVHF6.pdf shows a couple of RF
switches and a AD8307 log detector. The PLL synthesizers are up at 1+
GHz, so maybe there's a filter and mixer somewhere else. I couldn't
find a block diagram.

That's why farmers used horses and nowadays tractors to pull the
array through the ground. But you know farmers: they always
forget
to connect the feedline! That's why you never hear them on the
air.

Hi Gerard, and there I was, thinking it was because an
underground transmitting station needed an underground
receiver station. Thanks a million, now I know why
there are so few farmers on CB.

Hi Jim,
I'm way up in the NC mountains, so I cannot speak regarding the AA-200A
front end.
I know when I lived in West Palm FL, the MFJ was totally wiped out by a
nearby AM broadcast station.

Yah, on the low bands I sometimes have problems with a local AM station.
It's probably endemic to most analyzers.

My thoughts on the MFJ line of analyzers is that within their
limitations, they are very good. I bought one and it just works fine for
me. The original one I bought had a problem at around 10-11 months. I
think that someone was messing with it in a high RF environment without
the dummy load on the RF connector. Somehow got a major dose of RF. Sent
it back to MFJ,and the replacement works just great. I don't loan it out
any more.

My biggest con is that it uses a lot of AA cells, no big deal. I'd buy another one in a minute if needed.

My new loaner is an older MFJ SWR bridge - since that is what most people are worried about anyhow.

Just make sure you keep a dummy load across the RF jack when not in use,
it protects the input, and makes a nice little reality check. Aside from
that, it's a great little tool.

I slid Al tubing over the supports for my two meter quad except for
the last two inches toward the tip and I cant tell any difference in
operation VSWR is the same. AGC voltage on my receiver is the same as
usual for a local repeater. Whether or not the boom ends of the tubing
were connected together also had no discernible effect.

I read that article, too. 'Twas in an April QST back some years ago.

It isn't precision lab gear but it will pay for itself by saving you from an
early roofing job.

An external rechargeable battery pack will keep you from wearing out the
screws or risk leakage while in storage. These things eat batteries. I use
a gel cell in a fanny pack to the external port. That way I never have to
take it out of the case.

Put some grease on the case screws and use only 2 on each side.
After 10 years use the other 2.

C.I.A. Director Panetta is absolutely right when he says he wants to move his Agency forward, America faces a lot of issues right now, but some are from the past and will affect the present and the future of the Intelligence Community and here are some and that can be linked :

1) The Neocon and Oil Lobby's are constantly pushing for a fight against Venezuela and Russia as well as Iran , because as long as they are the " enemy " and " terrorists linked " , America has only one solid source of oil and gas : Saudi Arabia-Qatar-UAE-Kuwait and only one strategic partner in that region :Israel, so they all get all our money, our weapons and attention, and when will the D.C. Politicians explain this to the American people ? when ? that it's all a fabricated dependency to keep us addicted to these 2 lobby's ? when ?

about the weapons in the Colombia-Venezuela affair , they are old bazooka-like single-use rocket launchers that Sweden sold to Venezuela in 1983-84, and now some seems to have been found in FARC's hands, so after 25 years the neocon press (the editorials in most newspapers are controlled by the Neocon-Oil Lobby's) demands that Washington DC declares Venezuela a terrorist country ?

Rebels Obtained Arms Sold to Venezuela, Colombia Says ,NYT, July,28,08
http://www.nytimes.com/2009/07/28/world/americas/28Colombia.html?

The US Policy in Latin America has been a disaster for 25 years, we should have a US-Latin America-Brazil Conference with all the countries in the continent to start a new dialog, a new era, but DC is so incompetent and corrupt, they will do only what the Neocon-Oil Lobby wants : to keep all divided and fighting, so no change here, what a criminal shame !

2) The next weeks are vital for Health Care Reform, for National Security and Rule of Law : the Obama-Biden team must make very clear to 140 million US workers and taxpayers , as well as the huge retiree and disabled group, that

a) IF THEY LIKE WHAT THEY GOT WITH MEDICARE OR ANY PRIVATE PLAN, THE WILL BE ABLE TO KEEP IT

b) AND THAT PRESCRIPTION DRUGS WILL COME DOWN IN PRICE FROM THE STRATOSPHERIC LEVELS THEY ARE NOW

c) and that the multi-billion dollar levels of profits of
Pharma ,Drugs, Insurance and their top executives , as well as the
Drug ads costs and its tax deductions as business expenses , will come
down to earth ...

of course, not included in all this are the Federal employees and
Congress members who get what they call a "Cadillac" Health
Insurance , like P.Obama has the honesty to say : these amazing super
deals like the one he got are excluded, the fact is that Congress
members get what no one else gets...
the next few weeks of "explaining" is the make or break of the
deal.....President Obama also wants to end the 177 billion dollar give-
away to Insurance Companies under the Medicare Advantage Plan, which
is what the Medicare plan offers already, but will he get the Congress
to go along on this ?

d) another little detail is the constant cases of Pharmaceuticals
(hello ! Baxter Pharma , how you all doing ?) releasing tainted
vaccines to the public, but hey ! if we don't get sick, they can't
sell us the medicines ,right?

http://www.healthreform.gov/
http://edlabor.house.gov/markups/2009/07/hr-3200-americas-affordable-he.shtml

and more about Health IT software security, below at 10)

3) about Rupert Murdoch and the Rule of Law :

a) In the 90's , when the Tobacco Lobby was under attack for
the costs of emphysema and cancer by then President Clinton and the
Democratic Party members in charge of Congress , the top executive
Board members of Philip Morris Tobacco, Rupert Murdoch and Carlos Slim
Helu among others , were trying to find ways to stop the Legal
Investigations going on (international labs were popping-up with
modified special tobacco seeds with huge nicotine concentrations, new
addictive toxic substances found in most cigarettes were killing
laboratory rats in hours ,etc.) so one "plan" was the one proposed
by then a gossip and scandal writer working for Murdoch in his New
York City publications called Goldberg, and she had a young daughter
called Monica Lewinsky ,and while the West Wing of the White House
was run at the time by Rahm Emanuel and his partners, Monica became an
intern , put right in the center of the White House and was left
alone with the president more and more time every day until she got to
the core : the President's "personal" attention , the scandal broke-up
and the Murdoch TV and newspapers machine started to make millions out
of it, all the way to the Impeachment Proceedings....a huge
business ,a wounded president under control of scandal and a Tobacco-
Nicotine Legislation distracted .....

And now with the same "special team" inside the White House, we all
know that it's a matter of time before P.Obama, VP Biden and their
teams gets stuck in another "fabricated scandal" and to keep them
against the wall and under their control, that's how they always

operate : lies, theft, abuse ,extortion and treason , the usual...but as they say : do it to me once shame on you, do it to me twice, shame on me ..... and that's why is so important also to break the circle of corruption and AUDIT the Federal Reserve, this and a new team at the Fed would give the Obama -Biden team power to keep these criminals at bay...

b) Already the way Murdoch got the USA Congress to make an exception so that he could buy assets from G.M. as a foreign national, how he got satellite technology and TV Networks like Fox while a foreign national and they had to change the Laws just for him , how he got away with the Tobacco nightmare, the Lewinsky fabricated criminal fraud, how he and his papers pushed for the Iraq war (with Senator Schumer and Rep.Emanuel , among others, every week on them pushing the lies about Iraq among others) , how Murdoch's papers and TV covered-up the news about the initial march to Baghdad leaving behind warehouses full of weapons and explosives unguarded, how the Baghdad Museum was looted with military precision (and it wasn't the USA or Iraqi Military), how the contractors were losing billions of dollars in trucks and hundreds of thousands of automatic weapons and rifles in transit , and on and on, without a hitch -- we must remember that without insurgency (and armed and with weapons) there was no justification for multi-billion dollar no-bid contracts ... it's a very simple business formula -- it all shows to the world how Washington D.C. has been hijacked by Murdoch and his goons, the Neocon and Oil Lobby's , and it's a criminal shame and a real terrorist act, but will anyone in DC stand up for the Rule of Law ? no one.

even how he avoided taxes on many of these issues in the late 90's and early 2000's should get the IRS going, right? .....not with his friend Shulman in charge of the IRS , won't happen.

c) Rupert Murdoch is a personal friend of Maurice Greenberg of AIG and Judge Rakoff , and the fact that Greenberg fraud case l was in Judge Rakoff chambers has many people wondering, since they all are friends of way back, was there any talks among jurors and Judge and Greenberg? is there anything that we don't know that they know ? how can such a clear double case go in Greenberg's favor ? will the Justice Dpt. investigate ? will Congress ? will the IRS ? will the A.G.'s ? will anyone care ? no.

and in the SEC case against M.Greenberg, he gets a 15 million dollar fine and walks away with 2 billion dollars in AIG and CV Starr stock, and what's the difference in the "cooking of the books for profit " that he did as CEO and chairman of AIG and the "cooking of the books for profit " that others did ? many got 20 or more years in jail, why some go to jail and others get just a fine ? and even others just walk away with a 300.000 dollar salary.... eh! Rahm , like you at Freddie Mac ?

d) In the 9/11/2001 Investigation, Murdoch's friends Zelikow ,Lehman and Ben-Veniste (all the Robert Rubin apparatus)

were in the 9/11 Committee, and no one could believe it, since all are friends and partners of the principals in the WTC case : Silverstein, Goldman, Pacific Investments, etc., etc., and specially when : 1) we think about WTC - 7 , the huge third building and that collapsed on its own footprint without being hit by any thing or anyone, in a perfect symmetric collapse ,and still is a mystery to engineers and architects , 2) and while Silverstein had called 23 Insurance companies just weeks before the attack (the leases were signed just 6 weeks before 9/11) to open dozens and dozens of policies over just about everything in the buildings, and about all these issues the Murdoch Tabloid media kept silence refusing to Investigate any of it, and always siding with the Silverstein-Goldman demands for billions and billions of dollars in Insurance payments : the whole thing smelled like rats on a sewer feast , and they were and are feasting on the dead....will anybody ask ? no .

http://www.nyccan.org/
http://www.ae911truth.org/
http://911dvdproject.com/

e) in the 2008 Financial and Derivatives Disaster, the Murdoch TV and Media machine defended many neocons in Wall Street (in many Military-Security and Intelligence Contractors the key stockholders are his Hedge-Fund / Equity / Investment Partners : the war profiteers)
and that's why he bought the W.S.J., to cut-off some of the most deep investigative reporting in that paper about the Federal Reserve ,the Treasury, AIG, Bear Stearns,Lehman,Merrill and Citi and their links (they all did their trading and investing in partnership) and the ex-vice-chairman of AIG, Frenkel , and the ex-chairman , Greenberg , know a lot about it, but will any one go to the bottom of this ? and will anyone check the massive high-speed trading they were doing among them at all hours? with the inside know-how of some at the Fed? and that the WSJ was reporting before Murdoch took the paper over ? no.

so all in all, Rupert Murdoch may be a sharp operator, but for the community as a whole, he has been and is a total disaster, a nightmare for America and the world, but ....he puts his foot and money down and in D.C. you can hear all the pants and garter belts dropping to the floor, the screams and cries....he knows how to keep the DC darlings on a leash , and they like it , the incompetent traitors.

Right now, and as many in the financial areas are saying, many " Wind and Solar Power Projects " are being delayed or cancel due to financing problems, and its the Neocon Lobby of Murdoch with Sen. Feinstein , Feinberg etal and the Oil Lobby the ones pushing to slow or kill these Energy Independence Projects with " No Finance" , this "problem" and that "little problem", they want to keep the USA stuck on imported oil and gas and depending on the Middle East for back-up sources (Saudi Arabia-Qatar-etc. and one strategic partner,Israel,

getting all our money and attention) , and so the National losses are staggering and the National Security implications huge, but will anyone in D.C. stand up for America? no.

Unless a new generation of politicians and Americans gets elected , we will always have this abuse, the war profiteering , the tax evasion, the corruption and the criminal activity while the " old class " politicians bend over for yet another campaign donation and yet another Murdoch "nice story" in his Media.

4) in the N.Y. Times, "Power Shifts in Plan for Capital Calamity" , July,28,2009 ,
http://www.nytimes.com/2009/07/28/us/politics/28continuity.html? , we learn that in case of total disaster, the Chief of Staff in the White House, takes control of the Military Office...why ? a political appointee in control? do the President and the Vice-President see where they put themselves in relation to the Emanuel,Summers, Axelrod,Furman, Orszag,Geithner,Shapiro,Gensler , Genachowsky, Feinberg group ? a political-military-financial organized group gets to control the Military Office of the White House in case of total disaster? this is totally Un -Constitutional , but will anyone in DC object ? no !

here is an excerpt ".....Power Shifts in Plan for Capital Calamity.....WASHINGTON — A shift in authority has given military officials at the White House a bigger operational role in creating a backup government if the nation’s capital were “decapitated” by a terrorist attack or other calamity, according to current and former officials involved in the decision.
The move, which was made in the closing weeks of the administration of President George W. Bush, came after months of heated internal debate about the balance of power and the role of the military in a time of crisis, participants said. Officials said the Obama administration had left the plan essentially intact.

Under the revamped structure, the White House Military Office, which reports to the office of the White House chief of staff, has assumed a more central role in setting up a temporary “shadow government” in a crisis.

And the office, a 2,300-person outfit best known for flying Air Force One, has taken on added responsibilities as the lead agent in shepherding government leaders to a secure site at Mount Weather in rural Virginia, keeping classified lists of successors and maintaining computer systems, among other operational duties. Many of these types of tasks were previously handled by civilians at other agencies, led by the Federal Emergency Management Agency........"

5) WASHINGTON TIMES, June,23,2009 :
EXCLUSIVE: U.S. attorney nominee won't ID all clients
http://www.washingtontimes.com/news/2009/jun/23/attorney-nominee-wont-id-all-clients/
where we learn that Paul Fishman , nominated by P.Obama to be

U.S.Attorney in New Jersey , won't ID 37 clients of him at his law partnership , amazing,eh ?

and what about the 44 indicted corrupt figures in New Jersey? why the National Media is silent on this when at least 5 were involved in a Money laundering ring ? why not install the guy who did that great job , Ralph Marra Jr., acting U.S. attorney for New Jersey , in the permanent job ?

How is it possible that we find out about a very well organized money laundering operation working between the USA, the EU and the Middle East and the media turns silent ? how is it possible that c-span, npr and PBS don't even mention any of it?

and these same spin outlets, when P.Clinton secures freedom to 2 journalists , Ling and Lee, and out of North Korea ,they spin these great news into a negative gossip,a negative event, and hoping to minimize the success they look for arguments and conflict , and when they fail they go back to their warmongering criminal nonsense and lies , and they talk about patriotism? who are the real terrorists ? who are the real criminals and enemies of America ? what a criminal shame the TV and cable Networks have become !

6) Financial Crisis Inquiry Commission ,
http://www.opencongress.org/bill/111-s386/show
http://www.politico.com/news/stories/0709/25001.html
The problem is that the neocons will insert a neocon like Zelikow , Feinberg or Porter Goss to steer the Commission into another absurd 9/11 Commission : a cover-up and a distraction : ADD INSULT TO INJURY...

7) Schools with no playgrounds but with lots of vending machines for junk foods and sugar sodas, and then the parents have to spend money buying medications, and my question to Education Secretary Duncan and which so many parents are asking : When are schools in the USA going to have simple "Solar-Wind and Batteries" demonstrators in every schools so that kids can see how these new vital technologies work and to make them part of their natural growth: the new generations must be the leaders in Solar,Wind, Wave, Batteries and Hybrid-Electric plug-ins , fuel-cells, insulation, synthetic fuels and fusion energies, and the best way to grow a leader is to start early, by watching how these natural sources charge-up their gadgets and toys, their laptops and mobile phones, make it a second nature to them, a natural process ..... why not a simple "demo" in every school?

8) In the Criminal Anthrax issue of 2001 , when medical worker Nguyen was killed by heavy-duty anthrax spores at the Manhattan Eye,Ear and Throat Hospital, http://www.nymeeth.org/ , many knew that Emergent BioSolutions (the old Bio-Port from Lansing Michigan) and their executives, like Kramer, had a lot of answers, and then ...silent ! all the key Congress members went silent, no one asked about Bio-Port, and then they presented the usual gentiles as suspects: Dr. Hatfill

and Ivins, and the rest is History....until today, how could these anthrax spores get to the Manhattan Hospital ?

9) In the Internet video standards issue , Flash is "no good" for Mac or Linux, that's why we need HTML 5 right now ! we need code, tools, applications , solutions.
http://arstechnica.com/open-source/news/2009/07/decoding-the-html-5-video-codec-debate.ars
http://en.wikipedia.org/wiki/List_of_open_source_software_packages
http://www.w3.org/

at the other hand, this story should bring some joy to many:
"Google Chrome gets skins and JavaScript performance boost.
Google has released a new Chrome beta that includes a theming engine, faster JavaScript performance, several usability improvements, and support for HTML5 video. "
http://arstechnica.com/open-source/news/2009/08/googles-chrome-gets-skins-and-javascript-performance-boost.ars

10) And dear Director Panetta,the key problem in the Health Care Reform INFORMATION TECHNOLOGY CHOICE OF SOFTWARE is WHO is in charge of the medical private data ? , and do they have their own agenda ? who is watching them ? as usual, most of Washington D.C. is clueless, so who will ?

The White House announced that David Blumenthal, MD, was going to be the new national coordinator for health information technology at HHS, and he is in favor of proprietary software while the other Harvard University group that presented the better option was in favor of open-source, and Blumenthal's partners Genachowsky at the FCC, Leibowitz at the FTC , and Summers , Emanuel ,Orszag and Axelrod among others in the White House are insisting on using proprietary Flash technology from Adobe AND OTHER PROPRIETARY SOFTWARE, instead of the free and open-source HTML 5 that the web is based on, why ? at Flash ,where some of the top executives are, what a coincidence! , friends and partners of the above, they are very happy that they will be part of the "control" of all the data of all the citizens in America, isn't wonderful? and of course they will use Oracle from Ellison as database, right ? and if anyone objects, the SEC ,under supreme general chairman Shapiro -- the SEC ex-Commissioner that was in charge while AIG ,Bear Stearns ,Merrill and Lehman were selling hundreds of billions of dollars of Credit-Default-Swaps and she never saw anything !!! -- will immediately correct EVERYONE , if you know what i mean.....it's a perfect plan , wonderful, eh ? and the gentiles in DC ? many of them looking for a belt to hold their pants and garter belts , poor darlings !

So if you put all the dots together, the same organized people that gave us the 2008 Financial Disaster, will now control not only all the private data from all the patients in the USA , they will control also the software that runs the whole national system,amazing ,eh ? and later, when the "dungaroo" hits the fan, they will blame the Democrats and the Obama-Biden Administration, perfect ,eh?

In mi opinion, the sooner the Obama -Biden ticket gets all these neocons out of the White House and their Administration, the better, just look at the "dungaroo" they did Sunday, Aug,2,2009, when Geithner and Summers had the nerve to say on the TV "spin and lie" programs that higher taxes for workers and middle class are not out of the question , so dear P.Obama : when are you going to get all these neocons out ? when are you going to put an honest gentile in the Federal Reserve and audit that "cave" ? when are you going to get Flash out and low-cost HTML 5 video in ? when are we going to get going ?

http://www.ama-assn.org/amednews/site/mobile/content/ga0803.htm

Health Care Reform is vital, let's make sure the neocons don't control our data and software , because their Health Care Financial Abuse and Disaster could make the 2008 Financial Meltdown look like a little joke, they could wreck the whole country, the greedy fools ! , let's get it right this time !

And if you want to see what some people can do with our private data, just read this :
New U.S.-Israeli Crime Ring Detailed
http://www.nytimes.com/2009/08/04/world/middleeast/04israel.html?

11) And the "Standards" issue is an old one :Until 1995, the Defense Dpt. and all its units were using a mix of wireless radios, and then Qualcomm and Jacobs went to "advice" the Military in San Diego ,Ca. , and a few years later, many of the key CDMA and wireless radios used by the U.S. military and U.S. private consumers were paying huge royalties to Qualcomm and Jacobs, they showed up with all the patents, and even when these people got some good technologies, where are the Military and consumers radios that everybody was using as open-source and free of charge in the U.S.A. ? where are they ? .... many consumers and some politicians asked the San Diego based U.S. Attorney Carol Lam about this , but then she got fired and later became the top Lawyer in Qualcomm !!! what happened ? how is that possible ? and about the wireless radios and patents investigations ? nothing.

http://en.wikipedia.org/wiki/Carol_Lam
http://www.signonsandiego.com/news/metro/20070112-9999-1n12lam.html

Right now, America needs a massive push in advanced batteries and hybrid-electric plug-in systems as well as solar and wind energy, we are number 5 and 3 in the world in these key technologies, and that's a total disaster, and how can we spend 2 trillion dollars in the Banks and Financial Institutions (700 billion from TARP plus at least 1.3 trillion dollars between Treasury, Fed, FDIC and others) and then invest only 60 billion for all alternative energies and technologies ? and just a few billions for batteries ? we gave 180 billion dollars to A.I.G., the main promoter of this 2008 Credit-Default-Swaps Disaster, and for our own future and Energy Independence just a third of that ?

That's why also vital to Audit the Federal Reserve ,
http://www.ronpaul.com/on-the-issues/audit-the-federal-reserve-hr-1207/
and investigate the Organic Program Federal Law, where Senator Leahy
has worked so hard all these years,
http://www.washingtonpost.com/wp-dyn/content/article/2009/08/07/AR2009080703650.html
http://leahy.senate.gov/NwsLtr/20090327news_letter.html
http://www.nal.usda.gov/afsic/pubs/ofp/ofp.shtml

.....and now for the latest part of the Big Trick , "they" are about
to install new "old operators" in A.I.G .,Freddie Mac and Fannie Mae,
etc., and split , cut , divide and fire-sell their assets and of
course, Goldman Sachs, BlackRock,Pacific Investments,etal, will be the
key players, so after taxpayers INVESTED hundreds of billions of
dollars bailing out these tricks, the same old operators get to make
the cut AGAIN ! , and a big one ! isn't wonderful ? a triple whammy !
and Washington D.C. still looking for a belt to hold their pants...and
that's also why their stock is going up and up every day, they can
smell the roses already ...while the taxpayers will smell the !
$#&*XZ@#*! again.

in any case http://www.ilfc.com/ must stay in USA and EU gentile
hands, it cannot end up in the Middle East with our own oil-gas
money !!!

At least we also got Senator Webb that worked so hard for the Post
9/11 G.I. Bill, effective August 1,2009 ... that's leadership, that's
the real deal.
http://www.gibill.va.gov/
http://en.wikipedia.org/wiki/G.I._Bill

So dear Director Panetta, you are right to want to move your great
Agency forward, a very difficult job indeed, but we need a total clean-
up, and who will make sure that the old garbage is out ?

Thanks Owen for the information and your notes "In pursuit of dipole resonance with an MFJ259B"
My intended use for the device is to get a bit of view on what's going on with my various home brew antennas and matching devices and for my own curiosity to compare theory with real world.

I must admit I had assumed that the 269 analyzer display the sign of the reactance, I will have to reread the ad.

Ah, you were looking for honesty in advertising!

The online guff on the MFJ259B says:
"Read Complex Impedance as series resistance and reactance (R+jX) or as
magnitude (Z) and phase (degrees)."

The MFJ259B definitely does *not* show phase angle or reactance as
negative for cases where X is actually negative.

The same words appear in the MFJ269 online page, so it may also be a
misrepresentation.

I see in the MFJ269 manual, the same pretence over the sign of phase and
reactance. It contains the words "Besides Z, an angle between zero and 90
degrees is shown. This angle represents the phase difference between
current and voltage at the terminals of the analyzer."

Of course, a phase angle between "zero and 90 degrees" does not represent
"phase difference between current and voltage at the terminals of the
analyzer" in the case of a capacitive impedance.

Honesty in advertising... think again.

Owen

Again- look at the RigExpert A-200A. Batteries seem to last forever, it's USB upgradable and it DOES resolve the sign of R +/-JX.

Thanks Dale

I have just had a look at the RigExpert site. Look impressive, but the
MFJ269 at about $400US was about my limit.
I think I will take a step back and conduct a more scientific review of all
of the antenna analyzers on offer, there for you should get sick of my
postings over the next couple of weeks/months.
I must say that the ability to save and analyze data on the lap top is an
appealing feature.

Have a look at the AIM 4170 at http://www.arraysolutions.com/

I have that and a MFJ analyzer.

For a quick antenna adjustment, the MFJ is easier to use.

For in depth analysis, the AIM can't be beat.

If I had only one, I would prefer to have the AIM.

Or, for a non-handheld device, the TenTec TAPR VNA (Vector Network Analyzer) works quite well (albeit it, too, has a broadband detector). I've used it with both the PC software and CocoaVNA on a Mac.

The N2PK VNA has a more narrow band detector, but isn't available as a off-the-shelf box.

Kind of depends on what you want to do with it. I have a MFJ-269 (and a 259, as it happens), and it's a really handy tool when standing under the antenna or doing "pruning" and those sorts of things, where you basically are "spin the frequency knob and look for the dip". I don't know that I'd use it as a precision measurement instrument to measure inductors and capacitors. .. BTW, the whole "doesn't show the sign of X" isn't a big deal in practice. A small bump of the frequency dial shows that X is either getting bigger or smaller as frequency goes up or down. If your impedance is varying so fast with frequency that you can't figure it out, the MFJ isn't for you anyway, since it's a fairly imprecise oscillator anyway. If you are looking to do precision measurements of impedance at a bunch of points, as you write them down or plot them, it's obvious, and, in any case, it's not a great tool for that.

If you're looking to do something like adjust a phased array, you need one of the network analyzers. It's a lot better than trying to use this thing and opens/shorts, etc.

Peter,

It helps to identify what you really need from the instrument. The difficulty in doing that is foreseeing where an unstructured learning journey might take you.

You will tend to arrive a points where you want to measure something just beyond your existing capability. If the quest is for pure learning, then just concentrate on the things that are within scope, and enjoy the learning.

I admit that it is a bit of an old world view of ham radio, that it is quintessentially a technical learning activity... but call me a dinasour.

The resolution of sign with the '259B is not a show stopper, but it is a convenience issue and in the hands of a person with inadequate knowledge, it is potentially misleading.

TLLC (http://www.vk1od.net/calc/tl/tllc.php) can refer impedance made at one point on a known transmission line (eg the tx end) to another point (eg the load end). Of course, uncertainty of the TL parameters contributes to measurement uncertainty. This technique is ok for one off measurements, but would be very labour intensive for a sweep with hundreds of observations.

The ability to calibrate the feedline 'fixture' as part of a VNA measurement system provides the convenience of measurement referred to your preferred reference plan. The AIM4170 is (as I understand it) half

of a VNA, but that should be enough to do the same thing.

So, for the advantages of the ham grade VNA over the MFJ259B, you pay more money, get better measurement resolution (the AD converters have better resolution than the MFJ259B), have capability for automation of measurement referred to a convenient reference plane, but... you lose portability... though there is no reason why a ham grade VNA with a basic display system couldn't be portable.

Owen

The fixture cal is a pretty standard feature of all the ham VNAs (AIM 4170, TAPR VNA, N2PK) whether one or two port devices.

Making it portable is something I've been toying with.. The software is not that complex (at least for the TAPR VNA), so running it on a PDA velcroed to the top of the box isn't out of the question. One problem is that the TAPR VNA is a USB slave, and most PDAs can't be a USB master.

Maybe a small touchscreen netbook? Granted, you're now talking $1000 for the complete setup, but you'll have a real portable powerhouse, much like the Anritsu SiteMaster at 1/10th the cost.

http://www.us.anritsu.com/products/S331E_Site-Master-Compact-Handheld-Cable-and-Antenna-Analyzer_ARSPG_ARQQSidZ1016.aspx

I've also contemplated making something like a S-parameter test set for the TAPR VNA (so you can do both directions) with a built in eCal. Basically just high quality relays and terminations is what's needed.

Another useful add-on would be something that turns the VNA into a spectrum analyzer (e.g. use the output as the LO to a mixer followed by a BPF).. There's a lot of other problems with this, though.

And, _you_ are klewless, too.
The spam was a usenet post to the rec.radio.amateur.antenna newsgroup
from a google grooper spammer -- *NOT* not a posting on your sheltered
little "radiobanter" `forum`. The knowledgeable folk on usenet are
killfiling google grooper posts because of the spew of spam from there.
Obviously radiobanter.com does not care what sewage it sucks up off
usenet to feed to you folks.

As for the klewless on radiobanter.com... I've been selectively
killfiling the XXXXXbanter.com crap that get posted in other usenet ng's
for some time now -- photobanter.com, and some others. It looks like
it's time to killfile the idiocy issuing from radiobanter.com, too.

It would be nice if the sloppy-assed portal between radiobanter.com and
usenet was severed.

Hell, it would be nice if the sloppy-assed, spam-tolerant portal
between _groups.google.com_ and usenet was severed, as well.

And, replying to a drive-by, write-only spam post on usenet is a
useless, idiotic thing to do and only angers the rest of use that
have the good sense to use a good usenet service and employ a good
filtering system. We never see the original spam, but we have to
suffer through all the juvenile, (un)clever retorts.

I can't provide any info on the MFJ269, but I wonder whether the
MFJ993B automatic antenna tuner might serve a similar purpose, with
two big advantages over the 269. One is that it relies on your
transmitter rather than on an internal RF source so it is less likely
to be overwhelmed by nearby broadcast transmitters; and the other is
that it is also a decent antenna tuner.

The 993B uses some of the same circuits found in the 259. Of course,
there are some things the 269 will do that the 993B won't help with.

I have 6 sections of Rohn 25 set in a yard of cement. It is guyed at about 30 feet and about 5 feet under the top of the tower with 3 wires at each place. I need to remove the wires on one side so I can cut a tree to keep it from falling on the guy wires.

On top of the tower is about 15 feet of pipe sticking out. About a foot over the tower is a 3 element triband, and at about 5 feet spacing is a 5 element 6 meter antenna, two meter,and 432 antenna all on 15 feet long booms.

Will it be safe to remove the two guy wires on one side of the tower for about an hour to cut the trees, or should I let the tension off all the guy wires ?
This would be done when the wind is not blowing.

As you have probably guessed, guy maintenance on towers is a high risk activity. Lots of seriously large towers have failed because a single guy was slackened. The taller the tower, the greater the risk.

In any circumstance, slackening (or removing) one guy of a set will introduce a lateral force that bends the tower. With sufficient weight, that may lead to buckling and structural failure.

If you remove all guys in a set by progressively slackening each them, that may not introduce the lateral force describe above, but the greater length between existing supports may allow buckling and structural failure.

Can you remove all guys? Is the tower installation designed to be free standing at reasonable wind velocity?

The safe answer is to consult a structural engineer.

Can you remove the tree without slackening guys and without risking dropping parts of the tree on the guys? Perhaps cutting the tree into smaller lengths that are lowered to the ground on ropes to guide and slow the descent? I have watched tree climbers take huge trees down, lowering all the pieces in a very limited space against the trunk.

Have you asked your arborist about the removal and the risk to the tower?

Owen

Hi Jimmie

IME the most critical part of quad tuning is F/B so you might like to use that as a go/nogo test for your spreader experiments.

My thinking on metal spreaders would be about their length with respect to wavelength. ie if they started approaching resonance of the operating frequency (incl coupling to boom etc) I would expect pattern/gain & feed Z to be affected. I wouldnt try real hard mind you, just plug the think into a NEC engine.

Good news though..

Cheers Bob

Several things...There are silicones that have a non-acidic curing
process. They take longer to set and stay soft for their life.
That said, unless you have metal that is about the same thickness as
aluminum foil there is no way standard silicone is going to damage it
in 20 years or so. Yes I have been working with GE silicones for, oh
35 years or so.

Unless there's something you're not telling us about your operating,
there will be little or no risk of "arc over/breakdown" at the center
feedpoint.

Locate some 'aquarium grade', non-acidic _silicone_ "goo".

Unless I missed something when I described the tower, what is marginal ?
The first section of tower is set in a yard of cement as described in the
Rohn booklet. Also they only require two sets of guy wires up to 70 feet.
I live in the middle of North Carolina so a large build up of ice or very
high winds (say over 90 mph) would be unusual.

I'll second that. The AIM4170 *is* expensive, especially when you add on 15% UK sales tax (and it took me 18 months to take the plunge), but it does so much more than the MFJ units.

Instant computer readout, in nice graphical form, of all the antenna system parameters over any selected frequency range up to 170MHz. They claim to have interference reduction capability to minimize the effects of close AM MW signals, but I don't live close enough to an AM transmitter to test this.

The other nice thing about the 4170 is the ability to control it remotely. With the 4170 connected to the antenna system in the shack and controlled by a local PC, it's then possible to remotely access the PC from a cheapy notebook in the backyard. You can make antenna adjustments out in the yard and see the effects of the changes immediately, without having to repeatedly walk back indoors to look at the 4170 PC. This feature alone has saved me a *lot* of time:

<http://homepage.ntlworld.com/wadei/AIM4170/Remote%20AIM%20Control%20HOWTO%20-%20090106.pdf>

Well worth a look.

1313. Using A "Combiner" For A SDR

Newsgroup: rec.radio.amateur.antenna
Date: 2009-08-20 15:46:25 UTC
From: Robert11 <rgsros@xnotme.invalid>
Message-ID: <h6jr4m$e8h$1@news.eternal-september.org>
Source record: 13825

Hi,

Just an elderly sw listener from the old days.
Not very sharp with antenna theory, frankly.

Anyway, would be most grateful for any thoughts on the following, please:

Have 2 scanners working off of a single Scantenna antenna.
I now switch the Scanners via a good quality pushbutton switch which
supposedly is suited for the vhf/uhf range.
Seems to work fine.

Also have a hardware hf receiver, with its own antenna.

Thinking of getting a new "toy," perhaps a WinRadio SDR receiver.

Here's where the fun starts:

It only has a single antenna input, even though it has vhf/uhf capabilities.

They want you, apparently, to buy one of their Combiners for $ 200.
Ugh.

Take a look at: http://www.winradio.com/home/acd-1800.htm

Question 1:
Anything "better," or cheaper ?

I guess I will be forced to set up some kind of switch matrix, even if I do
use their Combiner.

Question 2:
But, the following problem arises, no matter how I do it.

The HF input, as well as the UHF/VHF input will at all times be "seeing" the
turned off hardware HF receiver (when using the SDR PC receiver) as well as
the turned off hardware scanner input (when using the SDR PC receiver)

In other words, each input to the combiner would be fed by a "T" where the
run to the hardware HF Receiver is tapped off to the Combiner. And the run
to the hardware Scanner is also tapped off via a "T" to the vhf/uhf input
of the Combiner.

From looking at the link above for the Combiner, and its specs, do you think
there will be any "meaningful" loss at the SDR PC receiver if I use it, and
it sees these not-in-use inputs also ?

And the other way around, I guess. If I am not using the PC SDR, will my
regular Scanner or hardware HF receiver suffer any from having the Combiner

in place ?

Tried to explain this as clearly as I could, but if confusing, will try harder if you ask for any clarifications.

Any other way(s) of doing all of this, that would be too complicated or expensive, perhaps ?

Thanks,
Bob

If you're worried about moisture getting into a coaxial feedline, I wouldn't settle for anything less than Coax-Seal (mastic tape) for a long-term hi-power installation. Proper installation of the coax-seal is very important, randomly gooping gunk around won't help much.

Don't worry about exposed connections to/from antenna wire. Just keep the moisture out of the coax.

If you're feeding with ladder line, I don't think there's anything that has to be waterproofed at all.

Some people like to spray with clear acrylic to keep things shiny but I don't think this will hold up forever in the sun, and it does nothing electrically, and might become a minor pain that you have to scrape off in case of modification/repair.

Hi Robert

As I see it, you are considering a very complex "radio listening system".
Aparently you are considering two or more receivers and two or more
antennas. That will involve lots and lots of compromises.
Is it reasonable for you to insert DC blocks in the antenna connections to
each receiver? If so, connect all the antennas and receivers any way you
want. If you get adequate performance, there will be nothing additional
required. As you experience performance inadequate performance, then, you
can investigate automatic (computer controlled) switching or "combiners".

Probably not, but hot melt glue is a better sealant and a better RF insulator. Regular translucent hmg is amorphous polypropeylene, a largely non-polar polymer which is a close relative to polyethylene. It is free-flowing and very, very sticky while it's hot.

Tapes are excellent for waterproofing simple shapes like inline connectors, because the tape can be applied evenly and under constant tension. But the tails on the end of coax make a difficult shape to wrap. The same applies even if you connect a plug to the socket on a dipole center insulator. These more complex shapes make it difficult to keep self-amalgamating tapes under the tension that is needed to make them seal effectively.

Coax-Seal is good for waterproofing complex shapes because it is moldable... but what are its RF insulating properties? I've never seen a product data sheet that deals with this issue.

I've had cables and connections sealed with hot melt glue outside for 10 years. Some applications involve high RF voltages where the hmg is the only insulation, and some involve very unfavorable combinations of dissimilar metals. In all that time I have never had a single failure involving either RF breakdown, water leakage or corrosion. Contrast that with silicone or epoxy sealants which begin to deteriorate after 2-3 years in the rain and UV.

Source record: 13832

Hi Robert

Good to see you on again! Yes quite a lot of endless possibilities!

It all pretty well boils down to how much loss you can "stand". Any unswitched configuration will lose at least half the signal in a 2 way split. This probably isnt a big deal at HF (since received noise is always much greater than the receiver noise floor), but may be "just enough" to cause problems at VHF+. Physical switches also introduce loss that varies with quality and operating frequency. One day too you'll want to have two receivers going concurrently and if you have a switched config will curse having it that way!

My suggestion? Check that there isnt any DC present on the antenna terminal of all your radios (that might be used for external preamps etc) and just hard connect the two scanners to the one antenna. Do some signal checks on a few known stations and see if you are losing enough to be troubled.

Do a few diferent evolutions to check the HF radio/antenna in tandam with the VHF/UHF system and standalone. I would expect problems here as some VHF/UHF antennas will look like dead shorts at HF.

If you have a signal generator set that up as a beacon in your yard. You may also be able to hear harmonic content to check up higher. (I often use the 5th harmonic of my HF radio to freq check my VHF radio, after having calibrated my HF radio to WWV)

Combiners are often transformers on toroids of varying sizes per frequency range. VHF+UHF combiners can be made of etched PCB's. You'll find quite a few designs in Ap Notes by the likes of Motorola if you look around. This may of course not be an option for you. Single frequency (+ odd multiple) splitters are much easier to build. All you need is coax!

In the end I would hope you can get away with low pass filter on the HF antenna (an old CB TX filter will do) and a high pass filter on the Scantenna (maybe a TVI filter meant for 75 ohm TV installs), a broadband combiner/splitter and 4 outputs, one to each RX.. You may even be able to use a CATV splitter. They supposedly work down to 5MHz nowadays (for cable internet upload) Thats about the cheapest I can think of, but of course there will be some loss. I dont think CATV splitters go past about 1GHz for example.

As to your off vs on Q2. In a theroetical world your splitter device would have a specfic Z and for max power transfer your receivers would have the same. It never happens that way in real life though. In your

case too you are receiving only so the problems become a lot simpler!
Yes you would lsoe a proportion of the signal. Only you can determine if
that is significant.

And to "meaningful" loss? Try it! Changing your antenna height may even
negate all the loss you are concerned about. Thicker coax may be an
option too if you are interested in a lot of distance UHF work. Then
again if you are that interested a preamp may also be in order!

Apologies for not being specific!

Cheers Bob W5/VK2YQA

Have you ever thought of using a patch panel. Use TV F female
conectors on the panel and and push on F connectors on the patch
cables. This will allow yo to connect any rx to any ant.

Jimmie

A vhf/uhf TV splitter would do fine for the VHF/UHF energy. I wouldn't be
too concerned about signal loss on HF as much and wouldn't worry about T
connectors. The noise is usually high enough not to worry about losing
some. The TV splitter won't pass the HF but it may load it so you may need a
combiner. The ones made for ham radios would be less than half the cost for
better than 40 db of isolation. Plenty enough for what you are doing.
Check the specs for your use.

Hi group,

I just returned from my two weeks in the mountains near Gunnison, Colorado. My best antenna was a 40m wire dipole strung between two trees, about 20 feet up. Yes, that's too low for optimum take-off-angle (TOA) but the mountains on each side were high, so I think I benefited from what would have been a deficiency on flat land. On Tuesday night, I surprised the local club by checking into our 40m proficiency net from up there on 7183. Good comms.

I had many other QSO's on 40, especially with the west coast, but very little action on 20, even when using a dipole cut for 20. I think the TOA was theoretically more nearly optimum for 20 but I was banging all my RF straight into the mountainsides.

I had precut the antennas and had a good match on both of them. I also brought precut element pairs for 15 and 10, but I never heard a whisper on either band, so I didn't install those antennas.

On the way home (San Diego) we stopped in Las Vegas and I tried another Tuesday night 7183 checkin from the hotel parking structure. Should have worked but I made a stupid mistake by hanging the 40m antenna off the west side of the parking structure. Should have been the south side. I proved that not much comes off the ends of a dipole.

Did that antenna really work hanging from the parking structure? Yes, absolutely. I heard a lot of other people on 40. Then, when I inserted my little tuner and checked 20m, I heard a VK about 5-7. Naturally, I tried him a few times but he was answering other people and I was sweating like a pig in the setting Las Vegas sun.

Finis.

Some of the non-acetic cure silcones are water based, and do not make good insulators for some days after application... so in that case, apply them well before you intend using them, and don't adjust the antenna until the sealant has cured.

In my experience, those sealants have not degraded when they become wet in service, so it appears a temporary issue until they cure.

Owen

Most TV splitters (those used for cable TV) are specced between 5 to
1000MHz. [They need to pass the return path signals between 5 and
30/40/50MHz.] They obviously provide full throughput down to 5MHz, and
are probably OK to around 2MHz.

Although they are 75 ohm devices, they should work OK where the
impedance is 50 ohms (which, in the case of SW receivers, is very, very

nominal). At HF, their insertion loss is around 3.3dB for a 2-way, 6.5dB for 4-way, and 10dB for an 8-way.

Owen I would never call you a dinasour or should I say from one dinasour to another! I agree with your sentiments entirely of ham radio being a technical learning activity.

For me the outlay for any antenna analyzer is significant, but I'm prepared to pay a bit for the instrument that covers foreseeable needs, but that will be as you say will cater for measurements just beyond my current capability.

Let the evaluation continue.

Regards

Peter

I tend to make my SWR readings right at the antenna, whenever possible.
That length of coax to the xceiver will only make it look better in most
cases.

On the "internets", there is always someone for whom your tower setup is
not acceptable. Doesn't matter how well made and installed, there's
something wrong with it, and it will come crashing down, causing you
great liability problems.

Anyhow, being that the tower and guys are part of a system, I'd either
have the loppers take the tree down in stages with sections roped down,
or install temporary guys. Th/e first method is much easier and cheaper.

One of the advantages of the 4170 is the ability to calibrate out the
effects of the feedline.

I have noticed that. No mater what you have someone usually chimes in that
it is not the best. I bet I could have said I put one section in 10 yards
of cement and had it guyed with a 2 meter ground plane on it and someone
would do the same. I was waiting on a comeback as to why it needed
improving.

Pix here:
http://home.earthlink.net/~ku4pt/images/Beams%20on%20tower/

I can not put the temporay guy wires on as they would still be where the
tree may fall. There are only 2 trees about a foot or so in diameter and
about 50 to 60 feet tall. Poplar trees without limbs for about the first 30
or so feet.It will only take a short to just cut them. I have seen towers
that don't look near as good stand up long times. I don't think it would be
any problem for the tower to stay up without guys if there was no wind. I
was hoping that someone on here had done something similar over the years
and could say the best way. Drop all wires , or just one side.

My only complaint is the little switch on the face of the unit that is depressed to enable measuring UHF SWR. It must be depressed ONLY if the unit is already powered up. If it is depressed before you power up, as I understand, some of the solid state parts may burn out when you power up. The 259 model does not have this problem, as it only measures up through the VHF range.

Operation is limited in the UHF range of about 415-470 MHz -- you can only take SWR measurements.

There is no penalty for going 75 ohm to receivers. In fact, the TV antenna might do better than a lower placed scanner antenna. Even though the polarization is wrong, the height makes up for it.

Extra plumbing adds up to loss though. You might find the switches better to your liking after all.

Another way is BNC connectors and swap things around at will. This eliminates all unnecessary losses in the system. We always seem to wind up looking for a better signal without leaving the chair and climbing the roof.

Mike,

With the 4170 I can calibrate the instrument to compensate for the feeder impedance. After calibration, the indicated impedance at the TX end of the feeder is actually the antenna feedpoint impedance. This makes life a *lot* easier.

Oaky, well good enough. My vertical uses a stub on the feedline, so I have to be out there anyhow.with a connector in the line. Seems like 6 of one, half dozen of the other situation.

The concrete might not be of good quality - Has a complte workup been
done on the composition? I thought not. Hell, that thing is likely to
fall, and completely obliterate a 10 block area! 8^)

That part I couldn't tell ya. Can you guy the trees so to speak? Get a
rope around them somewhere far up and cut to fall in the direction you
want? Pulling on the attached rope via come-along might send them where
you need them to go.

While I must disagree with my own offering below, I realize your situation and will offer a suggestion, anyway. I would loosen, slightly, the remaining two guy wires so as to not have them pulling tightly on the tower when the third one is removed.

However, I would be concerned with no guy at all in that side of the tower.... could you remove the guy in question and move it to a temporary anchor point still on the 180 degree side of the tower where it might still offer a minimal amount of support?... and could you use a temporty rope as far to the other side of the 180 degree side in question and set up a temporary guy there? Without ANY minimal support, should the tree bump the tower when it is falling, you could have a disaster without some kind of minimal insurance guys. Heck, even a 20 foot 2 x 4 braced against the opposite side of the tower might be better than nothing.

Ed the trees I want to remove are not close enough to hit the tower. The guy wires are almost 50 feet out from the tower and some other trees in between. My problem is there is a gap between some other trees and it is almost a funnel effect that will put the tree I want to cut almost on top of one set of guys. Something like the last 20 or 30 feet of tree could hit that set of guys.

I don't think I can move the guys that I want to take loose. They might still be in the line of fire..I will probably wait to cool weather gets here. Too hot for now when I can be inside playing with the radio.

That begs the question of why you asked.

You cannot convey all of the relevant information in your short posting. One of the things about hazard identification is the skill of a competent person looking throught their own eyes will see things that a less competent person will not recognise. Why do people drive cranes, cherry pickers etc into power lines, trees etc... most often because they didn't *see* them.

If I was responsible for an operation that involved loosening one guy, or one set of guys, or more, and there was an adverse outcome, a court of law would probably find that I was negligent as I ought to have been aware that loosening one or more guys was a potentially hazardous operation (I am a qualified Advanced Rigger in VK).

I doubt that claiming that I or others had done it before without accident would be an adequate defence.

That is not to say that loosening one or more guys guarantees failure... but lots of tower accidents are *caused* by loosening guy wires.

Dropping a tree or part of it onto a guy wire is also a dangerous thing to do.

Owen

Easy, yes. But If you're not careful, this can be a great example of garbage in, garbage out.

I frequently calculate out the feedline transformation when making antenna measurements. But it's essential that you realize a small error in estimating the feedline loss(*) or length can sometimes result in a very large error in calculated impedance. This is particularly true if there's a large impedance mismatch between the line and antenna. Transmission line impedance, which can vary a lot from the specified nominal value (I've seen +/-20% with coax, more with ladder line), also has an effect on the result. So whenever I need accurate results or whenever the line Z0 is quite different from the antenna impedance, I start by carefully measuring the properties of the actual transmission line I'll be using.

If you're not convinced, spend a few minutes playing with something like N6BV's TLW calculator that comes with the ARRL Antenna Book.

(*) Some simplified techniques ignore transmission line loss altogether. This can lead to very inaccurate results in some situations. And loss is often quite different than the specified value, so it really has to be measured if it makes a significant difference.

At this point, I'd be tempted to suggest tackling the problem from the other direction.

Don't just drop the tree in question!

Instead, do what's normally done if a tree needs to be removed from an area with nearby stuff-you-don't-want-to-have-a-tree-fall-on. Have a competent tree-removal service take the tree down, from the top on down... remove and lower the limbs and upper trunk in sections.

It may be possible to remove the upper portion, and shorten the remaining trunk enough that it will be physically impossible for that part of the trunk to strike the tower or guys when it's felled no matter how its fall happens to be channeled and no matter how badly it bounces.

Or, it may be easier and safer to just take it all the way down to ground level in pieces.

Yeah, this will take longer and cost more than just chainsawing through the base of the trunk and yelling "Timmmbbbbbeeeeerrrrrrrrr!", but it may cost less and be safer than trying to de-guy the tower. It'll certainly cost less than the consequences of having the tower fall down, as a result of deliberate guy removal/loosening or having the tree fall on it.

The 4170 makes this a lot easier as you can measure the feedline actual
parameters as well as calibrate out their effects.

Most of the new analyzers that do "fixture cal" actually measure the line, so you're not doing any estimating.

Somewhere in the future, as hams get more familiar with this kind of thing, I see folks installing a little relay box at the feedpoint of the antenna that has a short, open, and load, as well as the antenna.

I've done this with an RCS-8V, modifying it to add a noninductive 50 ohm load and to short one of the relays. I then use my VNA to calibrate the relay box (or, more accurately, to just confirm that the load and short is good enough) with a short test cable.

After I went through the hassle of modifying, I realized that I would have actually been better off to just get 50 ohm loads with PL-259s on them and PL-259 shorts. oh well, it's done now.

So anyway, the RCS-8V has 5 ports and a common. I hook the the feedline on port 1, the antenna on port 5, the short on port 2 and the load on port 3. (Sometime in the future, I'm going to hook a phase reversing transformer on port 4). By turning on and off the various ports, I can connect loads and shorts to antennas and/or feedlines or leave them open.

In a real fancy application, I'd put a remote controlled antenna tuner with a few extra relays in it at the feedpoint. Hmm.. another project to languish half completed in my garage for years.

Or, you leave the whole job to the tree removal company. Let them
decide how to do it, and their liability insurance covers the effects of
dropping a tree on the tower. They get to make the call about temporary
guys or not or chopping up the tree into chips from the top down or
having a 100 ton crane hold your tower up while the work is being done, etc.

(For that matter, I saw a very large pine tree being dismantled
yesterday, with a 100 foot crane reaching over a couple of houses to

pick up the pieces as the workers cut sections from the top down, rather than the lowering chunks down strategy.)

Recognizing, however, that the tree removal company is going to charge more, but maybe, they're confident. Or perhaps, one is hiring "Bob the guy down the street with a chain saw" to do the work, and YOU are accepting the liability and risk, so guy removal may be a prudent thing to do.

Overall, I think the take home message from all these posts is that

a) dropping a single guy (or multiple guys) is non-trivial, and requires some thought and planning
b) the odds of a strong wind coming up while you're unguyed is low, so a temporary guying system could be acceptable
c) there's a wide variety in risk acceptance strategies among hams

No, yagi beams are electrically '0' in the middle of the
elements, so there is no need to insulate the boom
from the mast.

> Are there any benefits in insulating the boom from the mast or
> not when mounting?
I can think of no benefits to insulate. NOT insulating has the
benefit that static can run to ground if the mast is grounded.

Log-per antennas should be insulated from their masts as the
booms are part of the feed, and should not contact each other
or ground.

I am causing TVI at the moment and I was told that if I insulated the beam from the mast and choked the coax just below the beam it would guarantee to solve my TVI problem and improve the efficiency of the antenna. What do you think?

It's a lot of work to drop the beam back down to ground level to do this.

The voltage at the center of the elements is supposed
to be zero. Therefore, the boom is supposed to have
zero potential and thus can be mounted to a metal mast.

It might be a good idea to drop the whole thing and make sure there is no
corrosion anywhere, even at the cost of replacing hardware and any rusty
masts. rust and corrosion can actually cause broadband noise and harmonics
that doesn't come out of the transmitter. Perhaps there is an issue with
your rotor?

Stop listening to those people who "told" you this and "guarantee"
(whatever that means) it as a solution.

TVI is most frequently caused by your feedline's proximity to RF
sensitive devices AND the presence of Common Mode currents on the
feedline. Put a choke on the transmission line at the feed point and
another choke one quarter wavelength away from the feed point towards
the transmitter.

This is a very common topic here and if you were to Google the group's
combined postings about it, you would find a world of education that
goes beyond this simple prescription. (Google the terms TVI and
Common Mode and Choke.)

Kind of off topic but maybe interesting.

In Sydney in I guess the late 70's two broadcast FM stations came online
on 105 and 106MHz (Approx). Their antennas were both mounted on one of
the big TV towers in the northern suburbs.

Individual tests proved positive, good range etc etc. When they were
both turned on however they caused severe interference to the AM BC band
(1MHz or so) and also the CH10 TV (212MHz or so). As I remember hearing
the fault was a rusty rivet holding some tower sections together.

This information is anecdotal. I havent verified it!

Cheers Bob VK2YQA

This is a dumb question on my part, but what you are saying is that the mitigating effects that the cable has on the VSWR, making it look better in general, can not only be calculated and "calibrated out", but that the actual SWR of your antenna at the feedpoint is then given?

As you get closer to 1.1:1 at the actual antenna, would accuracy then suffer? If feedline loss can bring an antenna that is not near that to a level approaching that, wouldn't it mean that teh calibration is somewhere in the noise?

Like I say, this could be a really stoopid question.

Basically what you do is calibrate the instrument at the measurement
point, whether that point is the instrument connector or at the end of
a length of coax.

You attach an open, a short and a known resistance; 50 ohms by default
but it is user definable.

The instrument than frequency sweeps and stores the results in a user
definable calibration file.

When you make a measurement of an unknown, you define which calibration
file to use and the instrument corrects the readings to display the
characteristics at the measurement point.

Given that this is a $500 insturment and not a $20,000 labratory instrument
there are going to be limits to how accurate all this is.

After having used the AIM for a while, my opinion is that it far exceeds
what is required for practical amateur usage.

If you want to see some actual numbers, you can find a comparison of the
results of an AIM 4170 compared to HP lab equiment at:

http://www.bnk.com/w0qe/AIM4170_page1.html

1362. BRS Media Inc. Named As One Of The 5,000 Fastest Growing Companies By Inc. Magazine

Newsgroup: rec.radio.amateur.antenna
Date: 2009-08-24 16:52:58 UTC
From: nicholasg980 <nicholasguida@gmail.com>
Message-ID: <94634380-abcd-4e82-87f6-7524bf137d42@c34g2000yqi.googlegroups.com>
Source record: 13774

San Francisco, CA. August 18, 2009 - BRS Media Inc., a diverse and growing media e-commerce firm that helps traditional and interactive media companies build and brand on the power of the Web, announced today that the company has been included in Inc. Magazine's 2009 "Inc. 5000" list of fastest-growing private companies in the USA.

With a tremendous increase in revenue of 88.7% over the past three years, BRS Media has the honor of being named to the annual ranking of fastest-growing private companies for a second year in row. In addition, BRS Media ranked No. 35 in the Top 50 Media Companies, that featured prominent companies like: FriendFinder Networks, 944 Media and Pinnacle Publishing Group.

"It is truly an honor to be named to the Inc. 5000 list for the second consecutive year, we're elated to be recognized among the top of U.S. privately held businesses," remarked George T. Bundy, Chairman & CEO of BRS Media Inc. "This prestigious distinction is a testament to our dedication to building a successful Online company that provides innovative, cutting edge services to our first class clients and prosperous partners worldwide. We look forward to even more success and growth in the coming years."

BRS Media has pioneered the 'multimedia' domain space since launching the .FM & .AM Top Level Domains in 1998. Since that time, BRS Media has been actively and successfully promoting and marketing dotFM and dotAM to radio and media companies around the world. Online Radio is among the fastest growing segments of the Internet, According to Arbitron and Edison Media Research, reaching 42 million Americans age 12 or older during an average week.

In April 2009, BRS Media announced plans to secure, operate and market the .Radio TLD. dotRadio will be positioned as the New Multimedia Domain for the On Air and Online Community. The plan to launch ".Radio" follows ICANN's (Internet Corporation for Assigned Names and Numbers) decision to expand the domain space beyond the standard .com, .net, and .org. Being called the "Biggest Domain Name Expansion" in the history of the Internet, the move is expected to open the top level domain space to an unlimited number of extensions.

About Inc. 5000:
Inc. 5000, an extension of Inc. magazine's annual Inc. 500 list, catches many businesses that are too big to grow at the pace required to make the Inc. 500, as well as a host of smaller firms. Taken as a whole, these companies represent the backbone of the U.S. economy. The

2009 Inc. 5000 list measures revenue growth from 2005 through 2008. Complete information on this years Inc. 5000 can be found at http://inc.com/inc5000 Inc. 5000 is a registered trademark of Mansueto Ventures LLC.

About BRS Media Inc:
Based in the South of Market district (SoMa) of San Francisco CA, BRS Media (www.brsmedia.fm) is a member of the National Association of Broadcasters, the International Webcasting Association and the Webcaster Alliance. Listed as one of the fastest growing privately held companies by the SF Business Times and Inc. Magazine, its portfolio of Online properties includes: dotFM® & dotAM®, domain registrar of premium multimedia .FM and .AM domains; dotRadio™, the new .RADIO top level domain for the On Air and Online Community; iDotz.Net domain registrar of all gTLD domains (.com, .net, .org), as well as, boutique domains (.tv .la, .im, .vc & .mn); @Radio.FM & @Radio.AM, free Web based email services and the ever-popular Web-Radio, the leading portal for "tuning in" Radio on the Internet. dotFM, dotAM and dotRadio are either registered trademarks or trademarks of BRS Media, Inc.

Not at all. Imagine that you have a very lossy line. You'll read very nearly the cable Z0 regardless of what's at the other end. Extreme changes in far-end impedance will make very little difference at the input end, so it's impossible to tell with any accuracy what's at the far end by looking at the near-end impedance. Another case to consider is one where the Z0 of the cable is very different than the Z of the load. In that case, a tiny change in line Z0, length, or loss changes the input Z for a given load Z. It can be impossible to measure the line length, impedance, or loss with sufficient accuracy to find the far end impedance with decent accuracy.

This doesn't mean you can't get measurements good enough for amateur or even professional use. But on the other hand, your measurements can be total garbage in spite of your cable measurements if you fail to realize just how sensitive the result can be to small errors. A careful experimenter will do a sensitivity analysis which tells how large an error in results is caused by an error in measuring the feedline or in the input impedance measurement, then the probable measurement errors are estimated to determine the probable error in the calculated result. While a mathematical sensitivity analysis is the rigorous way to do this, something like N6BV's TLW program is just fine for most amateur purposes. Or, if you're using one of the instruments that does the calculation for you, try telling it the line is a few percent longer or

shorter, or has a Z0 or loss a few percent different from what it said or you measured. See how much it changes the result. If the change is small, no problem. But if it's large, it means that extreme care and maybe some other techniques have to be used to get a good measurement.

Let me give an example, done with TLW. Suppose we're measuring the impedance of an antenna at 30 MHz through 100 feet of RG-8x. TLW gives these nominal values for RG-8x:

Z0 - 50.2 - j0.47
Velocity factor - 0.8
Loss - 1.926 dB/100'

And suppose that these are exactly what our measurement of the cable said. We measure 21 + j20 at the input end, and conclude that the impedance of the antenna is 374 - j84 ohms.

But suppose the measurement at the input end was inaccurate by about 5%, and that the actual input end Z was 21 + j20. Then the load Z is 322 - j105, about 15% off in R, 25% in Z. Or maybe the cable measurement was off by just 1%, and the cable is really 101 and not 100 feet long. In that case, the antenna Z is really 129 + j166 ohms. We're even on the other side of resonance from where we thought. Or maybe the velocity factor was rounded a bit and it's really closer to 0.81 than 0.8. How much difference would that small error make? Well, the antenna Z would be 53 - j120 ohms with our input measurement of 21 + j20!

So, what's the real antenna impedance? 374 - j84, 322 - j105, 129 + j166, or 53 - j120? You're fooling yourself if you think you really know.

It's easy to get lulled into believing that just because we read a value to six decimal places, it's accurate. But you're usually doing very well to get within a few percent in spite of all those digits. And when that few percent results in a much bigger error in calculated results, it's even more important to realize the limitations of your accuracy.

Corrections:

I apologize, and misinterpreted my scribbled notes. The conclusion is the same, but some of the quoted numbers are a little off. Here are the correct ones.

And suppose that these are exactly what our measurement of the cable said. We measure 21 + j20 at the input end, and conclude that the impedance of the antenna is 322 - j105 ohms.

But suppose the measurement at the input end was inaccurate by about 5%, and that the actual input end Z was 22 + j21. Then the load Z is 273 - j125, about 15% off in R, 20% in X. . .

When I inspected antennas, we had two multi-kilobuck "Site Master"
instruments from Anritsu, mentioned here, that had a set of calibrated
terminations. IIRC, to calibrate the unit(s), we had to connect the
terminations, a short, a 50-ohm resistor and a shielded open circuit, one at
a time, to the instrument and tell it which one was connected. It swept the
frequencies of interest and stored its own baseline behavior over that band
of interest. Then, anything connected to it was referenced to that
baseline. We could also store a range of sweep frequencies (usually by the
name or type of antenna we intended to sweep) and it would recall all the
parameters. Automated, repeatable sweep testing is not available (yet) in
lower cost instruments.

I presume we could have calibrated any given cable, too. (Never required by
our test memos.)

1370. Line noise

Newsgroup: rec.radio.amateur.antenna
Date: 2009-08-25 19:09:58 UTC
From: Rick <ricknj10@hotmail.com>
Message-ID: <aGWkm.802$5c6.485@nwrddc02.gnilink.net>
Source record: 13782

A few months ago we had a discussion going here about my line noise problem here in NJ.
I am happy to report the problem got fixed today, and K2XT is one happy Dude ! I further want to
warn 80 meter and 160 meter DX ops that I am back on the lower bands this winter, have QRO,
and so look out Baby, I'm going to be able to hear that DX!

In great summary what we found a couple months ago was, driving from my house along the roads near here,
we could locate line noise by using my FT-100 transceiver on different bands, in AM mode. Although the
noise causes me the most problems on 80/160 my attempts at DF'ing it on those bands were useless. On ten and
six meters the noise can be heard 1/4 to 1/2 mile away from the source. Switch to 2 meters and I could
get a lot closer where the noise originated, within +/- 100 yards or so. Switch to 440 and I could tell within a few poles.
Then as I reported before I built up a 440 MHz Quagi which enabled me to stand across the road from the
offending pole and definitely pinpoint it.

Here's where it gets interesting. The particular technician I was working with from the power company has
had great success using a hand held acoustic tool. This thing even has a gun sight on it to enable him to
pinpoint the offending insulator/lightning arrestor/bad crimp, etc. On this pole however, he couldn't get a
good reading. Today a crew worked on it, and finally determined it was a bad transformer feeding two houses.
I guess that explains why the acoustic tool was ineffective. I had the 10 m receiver here set so that when the
noise level dropped 6 db the squelch would close and so I was able to know instantly when they had fixed it.

This noise source was 1.2 miles from my house. Noise was S9+5 db on 80 m with a Beverage antenna,
S8 on 10 meters with a 3 ele beam. Having the beam indicate the direction to look was very important.

A very frustrating 12 months + 6 days from the time I first reported it. 80 meters right now sounds like there's
no antenna connected. This is wonderful.

The $600 TenTec/TAPR VNA does open/short/thru/load calibration with
sweeps, etc. I don't have the AIM, but I'll bet it does too. These
days, it's not a big deal to include it.

If you were getting clobbered at your distance, those two houses must have
had little or no BCB reception.

Thanks for bringing me into the present.

I have an analyzer already. When I drop it off the roof (inevitable), I will look at the TenTec/TAPR VNA.

Oh, yes! The "rusty bolt effect" is well known to those of us who have
worked US Navy EMI problems. I did it off and on for almost thirty years.
A non-linear junction mixes two or more signals and the structure involved
reradiates the sums and differences of the fundamentals and their harmonics.
The structure can be any topside metallic item or collection of items.

The result is a comb of frequencies which can cause widespread interference
literally for miles. In some cases broadband noise is also present. In
really bad cases, HF receive is effectively non-functional.

The solution is to bond or insulate everything topside in areas of high RF
energy -- eliminate as many non-linear junctions as possible.

I once had a cracked/cold solder joint in a 40m downspout
vertical that seemed to partially rectify the source
signal generating undesirable harmonics on 15m detected
by another ham 1/2 mile away. A jumper across the bad
junction cured the problem.

Thanks Roy,

My knowledge of the matter is at the noobie level, but given that loss eventually gets you reading only the Z0 of the cable, it's what I suspected. I hadn't thought about a big mismatch between the cable and antenna, so there's another data point.

I guess they kind of liked the Kenwood D-7XX series, eh?

Any rate, built in GPS is cool and has been needed for as long as HF and VHF rigs have needed USB ports instead of ancient Serial ports.

Looks nice, any idea on price?

Yup. Navy ships have from a few dozen to several hundred such jumpers,
depending on ship type. Many are welded but some are bolted, especially if
the object must be moved for use, etc.

I have heard that hams who use a tin roof as an HF ground plane are apt to
generate harmonics.

The similar FT-10R has a list price of 450 USD. I imagine the new
FTM-350 won't be far from this figure, but I have nothing to back this
up with.

Some of the towers and masts used for broadcasting in the UK have welded-on tabs that are welded together after the sections are bolted together. A particular potential problem has existed since Band II was extended up to 108 MHz: that of generation and radiation of IPs in the band above, used for VOR and ILS.

What's your feed / tuning arrangement?

Based on what I see on the page at

http://www.andrewscom.com.au/site-content-section-08-emtron.htm

the TEV-1 is simply an end-fed monopole/whip. Although it's described as "broadband" I rather suspect that it's no more broadband than any length of pipe of that length would be. It's going to need some form of wide-range tuner, and a good ground and/or radials, in order to work on multiple bands.

The Andrews page suggests four forms of feeding:

- with a wide-range "high-impedance" autotuner such as an SGC. In this arrangement, it would be acting as part of the long-wire antenna that these antenna couplers are designed for.

- With a 4:1 balun and a 50-ohm feedline, to a tuner in the shack. I'd expect substantial losses in the feedline on many bands.

- With a high-impedance (e.g. "450 ohm") balanced feedline to the shack, and then either a balun/tuner or (I believe) a tuner designed to feed a high-Z balanced line directly.

- Inductive match (i.e. base loading coil), presumably for a specific band.

I would guess that the simple autotuners built into many HF rigs would probably not have the range to handle this antenna on most bands... they're usually limited to flattening out relatively low SWRs, to keep the finals happy. You'll need some form of wide-matching-range tuner (e.g. a good external "T" or "L" matching box) to handle the wide range of impedances that this antenna is likely to present on various bands.

Hello, and I ran into this issue years ago when trying to measure high (>
10 or 20) VSWR loads (in this case out-of-band shipboard HF antenna
feedpoint impedance) connected via a length of transmission line.
Accurate determination of load resistance is difficult to ascertain under
these conditions. A 1953 AIEE (a progenitor of the IEEE) paper by W.W.
Macalpine, "Computation of Impedance and Efficiency of Transmission Lines
with High Sanding Wave Ratio" describes the problem.

I was, however, able to obtain accurate results when I included the small
imaginary part (frequency dependent) of the characteristic impedance that
is present in a low-loss line. Outside the high VSWR load issue the
imaginary part can be ignored. Sincerely, and 73s from N4GGO,

John Wood (Code 5550) e-mail: wood@itd.nrl.navy.mil

John,

If I understand correctly, Macalpine's work was in finding solutions given the computation tools readily available.

The approximation of a real transmission line as having Zo that is real can introduce significant error in some line calcs.

Improving the model to include an estimated X value based on the loss is a next step that improves calcs. This technique is widely used, and is revealed by Ro equal to the nominal Zo, whilst Xo is a small negative quantity for practical low loss cables at HF. This model produces significantly different results for high line VSWR at lower frequencies.

TLLC (http://www.vk1od.net/calc/tl/tllc.php) goes a step further and estimates a value for Ro based on the loss. For example, the Zo used for RG58 at 1MHz is 50.06-j2.31 ohms. This model produces significantly different results for extreme line VSWR at lower frequencies.

The more detailed models would be computationally unwieldly with log tables or a slide rule (the tools of Macalpine's day), but TLLC demonstrates that it is a trivial computational matter today, though not to lose sight of the fact that mathematical function libraries are often approximations favouring speed over ultimate accuracy.

Again, we must keep in mind that the uncertainty of the data fed into the model (including manufacturing tolerances, and through life component degradation) contributes to uncertainty of the output, and as Roy has

mentioned, the sensitivity of results to input data can be higher than people might otherwise expect.

Properly implemented, the VNA OSL calibration process and measurement process should overcome the problem of a sufficiently accurate model of the actual transmission line used in the 'fixture', though not the phase stability between calibration and measurement, especially where they are done under very different environmental conditions.

no solar activity... eclipse season maybe? for a short time each spring and
fall geostationary satellites happen to line up with the sun's path,
stations that have no backup satellite may lose signal when their satellite
lines up with the sun for a few minutes and the sun's noise blocks the
satellite signal.

Exactly right. Back in 1986, I worked for a bank data processing
service in Bellevue, WA. I set up a leased data line between our site
and two banks in Hawaii. The line went to San Francisco then via
satellite to Hawaii. Twice a year the service was stopped for about
1/2 hour while the sun passed through the focus of the satellite dish
in Hawaii. I don't think it affected the SF end of the link. AT&T
always called to warn of the disruption.

If the dish is pointed at a geosynchronous satellite, it should affect
both ends of the link, but at different times of the day. Actually,
for the typical DBS 0.7 meter dish, the outage appears for about 3-5
days and lasts about 5-10 minutes.

I live in a rather dense forest, where finding a "hole" in the tree
canopy for DBS reception is tricky. The best way to locate an antenna
is to check where the sun shines through the trees during the times of
the solar outage. Where there's light on the roof, there's a path to
a specific satellite. I've been posting bi-annual tables to help with
the calcs (when I remember to do so). For example:
<http://groups.google.com/group/ba.mountain-folk/msg/69c19369b4a5ffde?dmode=source>
It's also a good quality test for dish location. If the dish is
showing tree branch shadows on its face during the solar outage, it
needs to be moved (or the trees trimmed).

Assorted calculators:
<http://www.intelsat.com/resources/satellitedata/sundata.asp>
<http://www.satellite-calculations.com/SUNcalc/SUNcalc.htm>
<http://www.satellite-calculations.com/Satellite/SUNcalc.htm>
<http://www.ses-americom.com/americom_2008/siteSections/tools/sunoutage/index.php>
The Panamsat derived calculators have a bug in them where it will not
accept dish diameters smaller than 1 meter. For small 0.7 meter DBS
dishes, just use 1 meter and proportionally reduce the outage
duration.

This just shows that Foxtel's Public Media types don't understand the
technology that they use..... Sun Outages happen twice a year for a
couple of days in a row each time. The Sun's Track lines up behind the
GeoSync Sats position, in relation to the receiving Antenna, and the
sun's noise overwhelms the Signal in the receiver. This whole deal is
nothing NEW, just misunderstood by the Bloody Wonk, who wrote the Press
Release....

Let us put it into perspective. I used the term "sunburst" because I
thought it was an isolated strong sun spotas it is so early in the
cycle. But if they used the term sunburst as refering to its noise
level then no harm done as far as notifying the viewing public. Except
for me it appears that hams in general are aware of the true phenomina
and are not expecting the Sun to fall from the sky. A lot of excellent
explanations came thru and I enjoyed them. Ofcourse, if it a
subsidiary of FOX in the US then pile it on by all means
Thanks

Hi Paul

Just for interest what is the S/N margin with most commercial satellite systems and how "strong" is the sun relative to those levels? I would assume the margin for an end use TV viewer would be less than this?

Bob, it is a few years since I did satellite path designs... but relying on memory...

Most satellite TV here is digital, and the issue becomes a C/N ratio that delivers acceptable error rates after FEC. The characteristic has a knee, and error rates degrade rapidly at the knee. Satellite facilities are so expensive, that operation is usually quite close to the knee... save a margin for such things as weather, and that margin is usually no more than necessary for most but not all such variables. You don't need much Sun noise to ruin performance. (BTW, I think that the satellites used for this purpose here are bent pipe technology (aka linear transponder), the uplink is not regenerated on the bird.)

The issues discussed in the thread seem to mix up two distinct effects. If the earth station sees the sun behind the satellite, C/N may be degraded sufficiently to disrupt digital services. At equinoxes, the bird rotates into the earth's shaddow and some times of day, and that means it has to operate exclusively on battery, and if it uses the Sun for antenna tracking, it will need to change reference. Using CO2 for a reference (earth's atmosphere) is not reliable if the Moon appears from behind the earth, the antennas could track the moon. I am not up to date on the latest tracking references... but I am sure the Sun is still a good reference, good contrast, visible most of the time.

Owen

Don't know if they still do it, but once upon a time HBO produced a program guide for their home-sat subscribers. In the issues for April and October (I think) they'd always advise us about sun outages and give us the predicted dates, based on our latitude.

The Carrier-to-Noise ratio for analog TV was recommended to be 8db or better for a noise-free picture (~50dB S/N after demodulation). With my 10-foot dish, the peak of a solar outage would render the picture unrecognizable as such for up to a minute. This means the sun had to be about 4 dB stronger, since I recall 4 dB C/N was no picture at all. I hope this helps.

Sidelight: Analog degradation showed up as a type of video snow known as "sparklies," usually in brightly colored areas. The beginning of a solar outage would always be the appearance of sparklies.

I had the analog system for almost 20 years, so I was pretty conversant with these periodic outages.

Digital, I don't know. I have a small dish setup but I haven't played with it in years.

Sal

Gentlemen
! promised in the past that I would make details of my antenna
available to you in September, something I am not able to do now
My initial patent request at the moment is in the rejection mode.
Like many others of this group the PTO do not recognise the importance
of equilibrium with respect to the classical form of physics. In fact
they state that all can be pre anticipated as there are many antennas
that fall under such a scheme of things.
In addition, they are asking for changes to a drawing that does
not exist, either in my records or the web pre printed application.
Obviously they are in a pre mode rejection approach since I cannot
possibly accede to their request. Thus, in turn, I cannot release the
antenna replication information because of their actions with respect
to equilibrium .
I know that some will cry fraud but there is nothing I can do about
it.
I spoke to a patent attorney for the military who tells me that most
military
patent requests are initially rejected but they are easily reversed if
one
took on the labor of a beurocratic appeal for which I do not have the
funds or inclination.
The first patent request on this subject is on the web as Patent #
2008
655,899 I think, where Fig 3 is a computer info print out and not
accompanied by any such drawing which I am required to add to. If the
PTO changes its stance on equilibrium I will, of course, proceed with
sharing my antenna design work.
I expect that this posting will provide cat calls and insults but I
have been placed into a impossible position. If the patent office is
correct that all
shown is declared as obviouse then somebody, some day, will share with
the rest of the World and we all will be privy to much smaller antenna
designs.
If the past century can be seen as a guide I and many of you will be
long gone before this journey is repeated again.

Hi All

I have recently moved into Montgomery County Maryland from overseas (UK) and need to either identify a professional aerial installation company or some knowledgeable person to enable me to install a couple of antennas - an Alpha Delta DC-CC and a DIamond Co-Linear for 2metres. Support with siting options also probably needed.

Any idea welcomed.

Best wishes

Tom, W8ji apparently is an expert with antennas having lectured
at Dayton and has authored many technical articles around antennas,
states that radiators must be straight for maximum efficiency,
apparently
a break off from the standard ham statements of bigger is better as
well as more wire is better.
I have searched and searched for the reason why such a statement is
spread around as if it is has a factual or a mathematical statement to
back it up. For instance a quad radiator is not straight! Nor is a
loop or nor a helical as well as many others. At the same time it is
recognized that all is not understood about radiation and never has a
radiator been constructed that complies in its entirety with Maxwell.
I have untold books on antennas but none (not including ARRL stuff)
provide any sort of reason that this could be true.
Is anybody aware of a recognized author stating why this should be
considered true when current leaning is towards point radiation which
obviously seen as a break away statement..

Again, please provide a reference that "current leaning is towards point
radiation".

I sure I won't get a real answer here. As usual.

Just like his bailout on providing a description on his antenna earlier
this weekend.

fraud.

As long as you turn a blind eye to what he states
then you are in good shape! But then somebody in this group
will point you to Tom's statement and you can then respond as
to what he really meant which is not what he stated.

>
> > apparently
> > a break off from the standard ham statements of bigger is better as
> > well as more wire is better.
>

> And the physical reality that antenna performance is directly related
> to size in wavelengths.

It depends on your definition of "size". I prefer the term
encapsulating volume.
All physics laws are based on the presence of equilibrium. Thus you
may deform a radiator to the smallest volume as long as you retain a
state of equilibrium, regardless of the number of wavelengths at
issue. This is why "point radiation" is still discussed.
As an aside, the number of wavelengths used has nothing to do with
Maxwells equations
which accounts for ALL forces presence in the forming of radiation and
not the simple
radiator coupling and re radiation approach alone. It all comes down
to root L.C. in a equilibrium environment as the determinate factor
in his equations.

So, the bottom line is that you disagree with the statement made by
Tom as being incorrect.
It will be interesting what the rest of the group have to say as they
wade in.

Well, the only application I could find with 655,899 in it is a seat
belt buckle. I thought I was being helpful by reminding you of some
of the numbers. Numbers are always a nice thing to have. Do try to
recall your application number so I can look it up.

As for your difficulties with the USPTO, I have no idea what you're
talking about. If you need help obtaining a patent, the very last
place I would ask is the military. All their patents tend to become
classified, even if they're trivial. Unless your patent has some
obvious military significance, such as a plasma antenna, don't bother
with the military. If you go to NASA, they'll want the rights to sell
licenses for the technology:
<http://technology.arc.nasa.gov/partnering/licensing.cfm>

It's not terribly difficult to get a patent on your own:
<http://www.uspto.gov/web/patents/howtopat.htm>

<http://www.nolo.com/legal-encyclopedia/article-29493.html>
<http://www.ehow.com/how_4441109_get-patent.html>
and the usual YouTube videos:
<http://video.google.com/videosearch?hl=en&source=hp&q=how+to+get+a+patent>
in 20 parts at about 9 min each.

There's even fill in the blank software to make the necessary
documentation and drawings easier:
<http://www.inventorprise.com>
<http://www.patentpro.us>

If you can't get patent protection, you can manufacture your antenna
and protect the technology as a trade secret. However, that's very
difficult with antennas, as they're easily reverse engineered and
analyzed.
<http://en.wikipedia.org/wiki/Trade_secret>
Hmmmm.... are you planning to manufacture and sell your antenna?

He might have been talking about small antennas:
<http://www.w8ji.com/radiation_resistance.htm>
"Small antennas require extraordinary care to obtain high efficiency."
The 2004 Dayton PowerPoint presentation is at:
<http://www.w8ji.com/Dayton/Limited%20Space%20Antennas.ppt>
Using Google, I couldn't find any statement resembling the "straight
radiators" claim.

Ummm... fractal antennas are anything but straight and have the best
gain for their size of any antenna.
<http://www.fractenna.com>

Also, efficiency isn't everything. For example, the efficiency of the
typical mobile HF antenna is fairly lousy because the antenna is a
small fraction of a wavelength long. Still, it's the best that can be
done on HF without trailing a long wire to a balloon, and dragging a
grounding plate.

Art,
The only place I have ever read that on Tom's site is related to Beverage antennas- the statement is true, and for obvious (to most of us) reasons.

You are different, you are polite
Yes I will supply the patent request number and the subject is well
discussed on this group.
The bottom line is that the PTO does not recognize the term
equilibrium the same as most of this group. From my education a theory
is only that until it satisfies the laws of Newton
and Maxwell. The boundary laws are such that with classical physics
all laws deal with the Cosmos as a whole where balance or equilibrium

reins supreme. There is no law in existence that is accepted without
conforming to boundary laws which goes back to Newtonian laws. Now
equilibrium and boundary rules do not occupy the curriculum in the
U.S. I cannot explain why but this group and the PTO subscribe to the
idea that equilibrium has no position in this Universe, that I have to
accept even tho commercial computer programs based on Maxwell provide
confirmation of my findings. I can move on,no sweat

The PTO is losing examiners faster than it can replace them and this
is showing.
I want ham radio to serve those who are not equipted to join the
group. If I apply for a patent and thus reveal my findings and the
patent office does its thing then amateurs will gain by it but the
wolves are then able to take all. On this group there is denial of a
better way which is an obsticle all patent owners have to face so it
is better for me to stay silent and wait for a better environment to
provide my antennas. I have antennas that are way smaller than present
even a directive rotatable top band antenna and I am content as are
others I have shared with. While equilibrium in physics are disparaged
in the U.S. sciences
then I must be content with what I have! And I am as others are in the

denial of its possible existance.

Foundit. It's not on Google Patents for some odd reason.
See: Application Number 11/655899 or 20080231540 at:
<http://appft.uspto.gov/netacgi/nph-Parser?Sect1=PTO2&Sect2=HITOFF&p=1&u=%2Fnetahtml%2FPTO
%2Fsearch-adv.html&r=1&f=G&l=50&d=PG01&S1=655899&OS=655899&RS=655899>
Sorry about the giant URL. If that wraps or doesn't work, try:
<http://appft.uspto.gov/netahtml/PTO/srchnum.html>
and type in either application number. If you're going to refer to
your patent application by number, don't forget the 11/ prefix.

For some odd reason, I can't see the five attached figures. Probably
my fault (or Quicktime).

I suspect you may have some problems with claim 3.
"3. A clustered array according to claim 1 where the radiating
elements of said cluster have random three dimensional Cartesian
directional positions of placement with respect to each other and the
surface of the earth."

I don't think you can patent a random collection of elements as it
would be classed as too broad a claim. That would encompass all
antennas that were NOT designed according to non-random calculations.
While the use of randomness is possible (and common) in patents, I've
noticed that they always disclose the method by which the randomness
is achieved.

I would be interesting in seeing a photo, NEC2 deck, and test results
for your random element antenna. Take you time, no hurry.

The PTO has offered alternative claims but after trashing the request
such an offer would not stand up in court. True a lot of people are
just interested in saying they have a patent
but I am not willing to pay maintenance fees for something that does
not provide protection.
The killer of course is the allegation that I have not placed numbers
on a drawing which does not exist or was submitted from me. There is
no oversight or redress from an examiners descision and no discussion
available since he is not fluent in spoken English so time will run
out and it will be declared abandoned. Walter Cronkite had the phrase

that deals with such situations. By the way I use a program that uses Mininec as well as being an optimizer. I did have a academic in the antenna field confirm that my discovery was correct and provided NEC4 proofs which is what PTO accepts as a basic of proof. I got this confirmation not because I doubted what I had but it is the thing all engineers should do.
So my work will sleep with me at night and never see the light of day and hams can feel they have lost nothing. At present I have no antennas left to operate on.

Very true for electrically small antennas with emphasis on
electrically.

> <http://www.fractenna.com>
That is what Chip states for his company but I have no idea how a
fractal would work on top band. Most on this group deride the claims
of Chip with more than a handful of insults

>

Exactly because it takes a WL or multiple there of to attain
equilibrium

Still, it's the best that can be
> done on HF without trailing a long wire to a balloon, and dragging a
> grounding plate.

No. You are incorrect in my eyes! A multiple of a wavelength does
not require a ground plain and can be condensed into any shape or form
whilst retaining the required equilibrium. This is per the laws of
Maxwell when considering all forces involved in radiation for maximum
efficiency.

I know it is considered as obvious to those who resist change.
Obvious as you stated means that there is no possible alternative
available because all is known.

Well, suppose you show us for a given length Beverage antenna, how
configuring it in any other shape but straight makes it a better Beverage.

No. As I remember it he stated this to somebody on the Double Helix
question
on QRZ antenna design forum some time back. Last time I looked at that
there was several thousand viewers but nobody challenged him! I
believe it is some three pages back in the archives. I am sure he has
stated same in other places. If you ask him I am sure he will point
out the instances to you.

What person is this?

I ask because the phrase "military patent attorney" produced no results at Google. The phrase "patent attorney for the military " produces exactly one result: your post using the phrase.

Why involve the military at all?

I ask because the military doesn't buy from individuals. It buys from companies. Your antenna, whatever its ability to inspire wonderment (or not), will be developed and produced by a company that acquires rights to your eventual patent. (I have a passing acquaintance with military procurements, having worked on all three sides of that triangle: 21 years active military, 20 years defense contractor and five years Civil Service, including training for procurement.)

Last time I checked, we don't have a single "military". We have an
Army, Navy, Air Force, Coast Guard, and some other organizations, all
under the Dept of Defense. Each have their own policies for handling
patents. For example:

Office of the Judge Advocate General
Department of the Army
Intellectual Property Office
Regulatory Law and Intellectual Property Division
901 North Stuart
Street, Arlington, VA 22203-1837.

Basically a patent attorney. It's possible that Art talked to one of
them.

<www.army.mil/USAPA/epubs/pdf/p27_11.pdf>
Looks old, but interesting.

> I ask because the military doesn't buy from individuals. It buys from
> companies.

True. However all the branches will license patents from individuals.
If they want something manufactured by a 3rd party, and they need a
patent, they will arrange for licensing (or confiscation in case of
need or secrecy). I don't wanna get into technology transfers and
royalties.

Not unless it was at a bar and Art was buying.

A military attorney is not going to be talking to a civilian off the street.

Good info, Owen and it should be noted that "VNA" is a vector network
analyzer and "OSL" refers to the open, short, and load (usually 50 or 75
ohms) reference standards used to calibrate the VNA over the frequency

range of ineterest.

The small reactive (imaginary) part of the transmission line characteristic impedance is covered (as are all things to do with RF transmission lines) in detail in R.W.P. King's seminal work, "Transmission Line Theory". King also covers transmission line baluns in depth. 73s,

Greetings, Andy, and as I reside in the metro DC area (Arlington County,
VA) the first thing you should do is check on the local
ordinances/homeowner association restrictions on antenna height, etc. A
ham buddy of mine in Vienna, VA, had to cut his planned tower height "down
to size". Of course in the case of an outright ban on outdoor antennas,
you could always go with the vertical inside the pvc flag pole.
Sincerely, and 73s from N4GGO,

Art -- how, then, do you account for the fact that a 1/4-wave monopole and r-f ground system used by many AM broadcast stations produces radiated fields that have been measured to be within a few percent of the maximum possible for the applied power?

If "equilibrium" takes a WL or multiple thereof, why are such fractional wavelength radiators so efficient?

I can't think of a single patent where I work has applied for that was
classified (hint, US Navy R&E). I strongly doubt that anyone would seek
any patent that had classified details.

In industry, one uses patents and trade secrets to protect intelectual property. Patents have to be written in such a way that someone "skilled in the art" can duplicate the idea.

I'm not sure of the current state of US patent law, but in general it was intended that someone would read a patent, build the device and improve it. The improvement would be a deriviative work or it may be something new.

In either case, the original work, or a derivative work would be the exclusive property of the owner of the patent for a length of time, now 20 years from first publication or date of filing (whichever is earlier) in the US, and 21 years in the rest of the world.

Trade secrets are different, they rely on things that have never been revealed. For example, the formula for WD-40, Coka Cola, or KFC breading. KFC is an interesting combination, the process was patented, the formula was not.

So you can duplicate KFC chicken at home and now that the patent has run out in your restaurant in theory, but in practice, you can't because you don't know for sure what the ingredients and their proportions are in the breading.

There quite simply is no need to seek a patent with classified details. It's similar to a trade secret, but instead of contracts and ethics protecting it, the secrecy of it is protected by law.

There is also a law going back to the time of Lincoln administration about developing things under government contract, patenting them and then dedicating the patent to the people of the US. There is a big tax advantage, if it interests you, look up the details.

As far as radios are concerned, one could have patented a transformer consisting of a toriodal core of powdered iron and other materials (aka ferite) without revealing the other materials.

If that had been a "secret" invention, then others could duplicate the device but without the formula for the exact compostition of the core, no one would get the results you did. That's a two edged sword, they may be better at it. :-)

Note that this is just an example, I really have no idea of who invented the toroid transformer.

Geoff.

Hello,

Saw this Dynex Switch, and was wondering if anyone might "guess" as to what
its usable frequency range (receiving only) might be ?
Thinking of it for switching antenna inputs around.

Or, is it just too cheap to consider for any sw HF (or scanning freq's)
application ?
My guess is that it is, but thought I'd ask anyway in case someone here is
actually using it.

I'm not too sure what S Video freq ranges are.

Many Universities have near to them a quasi military funded work group
that employ some of the graduates of Universities especially in the
computer area.
The funding by the military is for different projects that they have.
These units
are monitored by patent personnel a couple of times a year where
information is gathered
for patent potential.Usually they do mundane computer work but there
are exceptions and there is some turn over as the graduates leave for
new found jobs. There are at least two such units that are in driving
distance from me that I know of and there may be more as there are
many Universities close to me.
I never said I consulted him or asked for assistance.
In these sort of discussions in this group small things grow so large
that they have a life of their own that often stray from the truth.

One time response
Most hams are aware there are two basic resistances or impedances
involved in any antenna. The d.c. wire resistance is a constant
whether it is above ground or not.
Radiation resistance only occur when radiation is allowed to take
place which usually is considered above ground. When the circuit
cannot radiate such as in a ground plain or similar then the circuit
does not encounter radiation resistance thus the only resistance
encountered is the dc resistance which means it draws less power from
the source.
Thus for a half wave with ground plain it will draw 1/2 the power from
the source that a full wave will. So when talking about efficiency per
unit of energy supplied the only difference
between the two is the wire resistance that is not accompanied by
radiation which is extremely small. So overall efficiency changes of a
radiator is so small it really is of zero significance. What is
important is the ability of an antenna to radiate maximum strength
where you want and the ground plain applies a limitation which many
can live with.
The importance of efficiency is that one is accounting for all forces
that impact it where you enter a different mathematical areana which
opens up clues to the formation of radiation
and possibly other scenarios that can be of benefit in other areas.

A case in point. If one has a vertical then the radiation pattern is
donut shaped ie it has a hole that is devoid of radiation which is not
so good for military servalance. This is because the radiator is
oriented opposite to the gravitational force only. If one wants to
account for ALL forces involved then one must include with gravity the

Corriolis force without which NOTHING can be stable on Earth. One must include it when considering the Earths forces within a arbitrary boundary to achieve equilibrium. Thus to be in equilibrium a radiator must be tipped to include the Coreolis force which then allows for a spherical radiation pattern ala Poynting's vector where the forces within the boundary equals (and opposite) that outside the boundary and is in a state of equilibrium Thus when a radiator is tipped it now fills up the hole in the donut to obtain radiation that is equal in all directions(equilibrium) which is what a military installation would prefer as possible observation is 100 %. Thus starting with a single radiator that is in equilibrium you are starting from a different point to a planar mode when proceeding with array designs which then becomes educational with respect to possible occurances that are not available to systems outside that of the equilibrium.

I beg to differ. There are over 4000 classified patents, 88 of which
are by the US Navy:
<http://www.fas.org/sgp/othergov/invention/stats.html>
(Note the classification of patents of private inventors). In FY08,
the Navy apparently applied for 8 classified patents. Obvious, I have
no clue what they were for.

More:
<http://www.uspto.gov/web/offices/pac/mpep/documents/appxr_5_1.htm>
<http://en.wikipedia.org/wiki/Invention_Secrecy_Act>

Drivel: I sorta blundered across this one. The patent is fully
disclosed, but the title is "classified":
<http://www.google.com/patents?id=kG-oAAAAEBAJ&dq=2008/0047450>
Oops.

>> Unless your patent has some
>> obvious military significance,

Some horror stories where key commercial technologies somehow get
classified. From 2002:
<http://www.spiritofmaat.com/archive/feb2/vesprman.htm>
"As a former Patent Examiner, I can tell you that the number
of 'secretized' patents in the vault at the Patent Office
(Park 5 Bldg.) is closer to 4000 or more. They [applicants]
never receive a patent number, and the inventor is rarely,
if ever, compensated by the government for use of the
invention."

That's an interesting question. Normally an inventor is not compensated for the use of their invention, as it were, by an employer. In most cases the employer owns the research it funded and the results (including patents) of that research.

Quite often the payment for a patent was one dollar. The late father of a late friend of mine was one of the inventors on 18 patents filed by RCA, 9 of which he was the principal inventor. From what I remember he received besides his regular salary, an offical payment of $1 for the rights to each of them, and a nice little plaque for his wall.

In some exceptional cases, usually where the inventor is a noted expert in the field before employment they negotiated different terms. There were also independent inventors who filed "invention disclosures" and then attempted to sell the invention to investors or companies in the field.

This has pretty much disapeared in the US as people now file provisional patent applications and market those. The problem of this system is that abandoned provisional patent applications become public domain when they expire (one year after first publication or filing, whichever is earlier) and invention disclosures, never being publicised could go on forever.

The other question I have is if a patent is filled and never publicised, how does one know it exists? If someone else invents the idea (actually very common) and files a patent are they refused? Are they sued for infringment?

Wow ! You are way out of date with respect to PTO procedures on so
many things.

The main thing is patents have stopped going on for ever. The primary change you have
that affects patents today is that patent request are pre printed for the public before they ever reach an examiner. If I understand correctly not receiving a patent leaves your request as a free for all in terms of use. The courts have now put more power in the examiners hands and are less interested in cases challenging the aproved claims. For your interest antennas have come to the fore because Chip has sued many cell phone manufacturers for knowingly using Fractal patents. It will be interesting to see how the courts handle this in the light of the many patent changes. You are now seeing more generic drugs over the counter as drug patents are not being extended for minor changes. Thus drug companies are using other methods to preserve their interests via import rules to stop generic drugs coming in from other Countries covered by the world patent office org of which the U.S. is part. This does not include Peurto Rico where many U.S. drugs are manufactured today

It would assist us if you would cut and paste the quote from Tom' site.
As I said before, the only place I ever saw this was with reference to
Beverages- the statement is true and obvious to everyone except perhaps you
Art.
The onus is upon you to prove that a Beverage in any other deployment
except straight would be better. I don't want to hear about your theories
that only you embrace- a simple EZNEC model will be sufficient.

Well not really. First of all an invention disclosure could go on forever
as I said because it all is based upon date of filing, or if nothing is filed,
date of first publication. If a person submits an invention disclosure to
an investor or prospective purchaser that is done with an agreement of
confidentiality, not publication.

Therefore an invention disclosure not being filed with the USPTO, or publicized
is not limited by the one year limitiation.

In the US, patent applications are published immediately. The USPTO has a
short period to reject applciations out of hand, and if they do not they
can be published as soon as the USPTO can, which I know is kind of vague.
However, you may request that the application is kept confidental until
18 months from date of application.

In the current environment, applications will be seen by an examiner in
around 18 months, so it may or may not be the case. It depends upon the
queue.

> If I understand
> correctly not receiving a patent leaves your request as a free for all
> in terms of use.

Yes. However you have a year to appeal a final rejection.

> The courts have now put more power in the examiners
> hands and are less interested in cases challenging the aproved claims.

I can't say anything about that, I have never dealt with the courts.

> For your interest antennas have come to the fore because Chip has sued
> many cell phone manufacturers for knowingly using Fractal patents. It
> will be interesting to see how the courts handle this in the light of
> the many patent changes.

Yes. In this case it may depend more upon the quality of legal representation
and the authors of the original patent applications. If Chip's patent
applications were written well, he may be able to prove infringment. If they
were not, then the likelyhood of him getting anything is small.

It would depend, IMHO on Chip's lawyers making them feel he is being vicitimized by the big bad cellular companies, or the companies making them feel he is a crackpot inventor who patented something similar, but not the close enough for them to pay him.

I've read an article foisted upon me about software patents that claimed they were bad because judges were unable to understand them. IMHO bad judges do not mean the whole system should be thrown out. I also expect that if the case were to go before a jury, it would be next to impossible to convince them of anything on a technical basis.

I was then told that I should read the paper's authors book, but to me it seemed ironic (and stupid) to pay $22.50 and postage to be told that my ideas should be free, while theirs were not.

> manufactured today

That's a special case. Most generic drugs come from Israel, which follows FDA regulations and respects international patents, and India which does not. Indira Gandi was presented the case that drug patents were racist, because they prevented brown (Indian) people from buying drugs sold by price-gouging white people (ICL in specific).

She allowed that the process could be patented, but not the product itself, allowing Indian manufacturers to make generic drugs without using the approved processes, and not subject to any quality control or testing.

WIRED did an excelent article about it a few years ago. If you want more information, I suggest you look it up.

As for Puerto Rico, it is part of the US, and since the 1970's has become a haven for drug manufacturers because of the low taxes. The FDA was (is?) loath to approve drugs which they can not supervise the manufacture of, which they can do in Peurto Rico, but not in other countries.

Then by your theory does the radiation launched by a vertical, 1/2-wave, center-fed dipole have a different pattern shape when that dipole is tipped away from the vertical plane?

I'm referring to the radiation pattern of the dipole itself, not including any reflections.

Dale I am happy with the responses of the group. Seems like they are
united against the idea that radiators must be straight for maximum
efficiency. I never mentioned anything about Beverages, that was
somebody else. As far as Eznec is concerned I am not familiar with it
as I use a program equiped with an optimiser that tries to bring your
inputs in line with Maxwells equations. For instance, Eznec is only a
calculator devised to provide answers to that supplied with additions
to handle planar forms that are not in compliance. When you have an
optimiser and your input is not pre guided ,such as a planar input,
the optimiser will respond with a non planar design that includes
the
Coriolis force such that Maxwells equations are enforced , and that
requires equilibrium.
That also means the programs costs more but all antenna design
companies use them as they recognise the true value of adherence to
Maxwell's laws.
The above justifies my position on radiators unless you want to
declare "garbage in garbage out". I have a simple sample printed of a
computerized array that shows the above in the patent request that is
presently due for extinction. The military uses tipped radiators in

many places to gain coverage of the donut hole as I have shown, but you will not see printed matter on the subject except from me. The WWW changes a lot of things regarding secrecy. Remember, when Tesla died he was working on a cheap energy system. The FBI raided his lab and took every thing which even now has not seen the light of day!
I know. YOU now want me to provide a copy of the statement to you but then,. you can choose to believe or not to believe and use free speech to demand any thing. But I am not in your employ.

Here's my understanding, based on what I've read about this general class of antenna over the past few years.

I'll have to let someone with more math knowledge than I speak about the specifics of the claims in this paper... it goes beyond what I've studied. Pretty much everything I've read, says that these claims depend on a rather different interpretation of Maxwell's equations than mainstream theory utilizes. The general conclusion I've picked up, is that you can't generate separate and independent E and H fields (and then combine them) in the way that EH-antenna theory claims.

As far as I know, well-controlled practical experiments to demonstrate the benefits of EH-type antennas have not resulted in success. The antennas "work" to some extent - that is, you can get them to radiate, and can achieve an impedance match - but the same can be said of almost any kind of radiating structure. The claims of exceptionally high electrical efficiency (for such a physically small antenna) don't seem to work out, though.

In practice (from what I've read), EH antennas seem to behave like other physically-short dipole antennas which are brought to resonance by means of a large amount of capacitive end-loading. As such they have a rather narrow SWR bandwidth, a low radiation resistance, and the risk of high losses (both in the antenna itself and in the matching network).

Tests of these sorts of heavily-loaded antennas can be misleading, unless you take care to decouple the antenna very carefully. If you just hang an antenna of this sort on a mast and feed it directly with coax, both the mast structure and the feedline can act as part of the antenna system, with significant RF currents flowing on them and quite a bit of RF radiation taking place. This can make the antenna "look

better" than it actually is. Placing the antenna on some sort of insulated mounting, and using an effective current choke at the feedpoint, is necessary to distinguish the antenna's own electrical characteristics from those of the support structure and feedline.

There are some commercial HF antennas which make claims similar to the EH type - e.g. the Bilal Isotron family. The instructions for some Isotron models say that they *must* be mounted on a grounded mast for proper operation... which leads me to believe that radiation from the mast and feedline are probably an essential part of their operation.

Hi Art,
I just want to make sure what you are quoting from ToW8JI.
So, if you have the time and inclination, please cut and paste Tom's
comments about straight radiators so we can all be on the same page.
I was the one who initially mentioned Beverages- because, although I am not
an expert on Tom's site, that is the only referecne I recall about straight
wires on his site.

Yup. Basically Hatelly is trying to find the "weak force" as predicted
by Einstein so that is why he is attempting to combine E and H forces
in the hope that more light is provided
to the phenomina of the addition provided by Maxwell which as yet is
not fully explained
in the books. Tom did some work on it and stated that it was the feed
line that did the radiating such that it was the system that was
providing the radiation and not just the antenna. Personally I don't
care what parts contribute to the radiation as long as it goes where I
want to put it. The bottom line is that Hatelly and Gabrera of Egypt
made an antenna but not the one they hoped for. However, I have, but
it is still in limbo because of PTO activity.

news:h7g797$g7l$1@nnrp-beta.newsland.it...

I thanks people that until now reply to my post.

It's quite clear for me, an Richard and Dave wrote, the true radiating points of an EH antenna, basically the feedline an also imho via groundwave with the grounding system, especially on lower frequencies.

What i'm asking is not a *complete* explaining of Maxwell equations in few posts, and why in this specific case can be right or wrong the paper.. just from the guru of this ng a simple "yes, he wrote in the paper a right interpretation of Maxwell equation and, in theory, the thing can work" or a "no, he's worse than a 1st april fool".

Like the precedent post on underground antennas systems, i'm just curious and happy if someone *demostrate* me that a strange antenna have a incredible efficiency. But the demostration must be in a understandable way for me, and if i don't understand, i ask to who can understand and had the patience to explain.

Sorry, btw, for grammar & language errors.

Good luck. As I previously ranted, the obvious stumbling block is the
user of the term "random" array of elements. If the examiner
interprets that as "arbitrary", then your patent is too general to be
considered passable. You might what to look at other patents for
antennas at:
<http://www.google.com/patents/>
Ignore the applications and concentrate on the patents that have been
issued. Compare these patents with your application. You should see
fairly quickly what you're missing. (Hint: References and Citations).

Oddly enough they (PTO)have offered claims with "arbitrary" involved
I say that is not bad since the positions are arbitrary but dependent
solely
on equilibrium where all are resonant, as is the enclosure, and can be
chosen as the feed..
all of which is determined on weighting applied which provide multiple
arrangements.
It is possible that if more radiators are added then one may not be
resonant and the boundary close to fracture. It is important to note
however that tho the majority will be resonant some will have a
impedance that is too low to feed. As can be seen from the above, for
equilibrium there are no compelling reasons for the elements to be
straight
We have to wait to what the supervisor has to say and what options are
available
Accept or role it in to the followi up application which is in the
same antenna catagory, the latter I am hoping for as it cuts down on

maintenance fees.
Regards

Not bad David. I suppose that can be seen as more modern than
equilibrium used centuries ago. Actually isotropic is presently used
more by cosmopologists when refering
to matter transformations and thus include the latent energy transfer
Very good, Now you are on the same road as I (I think) at least until
the next insult. (grin)

Hi Mac

The plan is i get a couple of Antennas up, get into the swing of US procedures via listening only (i am know DX well but interested to see local nets etc) and then get going on my exams / tests. I just want a wire Antenna and a small co-linear for now. Thanks for the X towers link. In the fullness of time i would like something like this but for now it will be something a bit more discreet / simple.

Best wishes

Andy

Hi John

Thanks for the helpful notice. I think we have found a great place for discreet antenna placement as its a 170'+/- yard which is moderatly wooded so will hide most of a wire antenna. Some issues about how to best position it. Also its a rented house so i know the owner / neighbours wont be keen on anything not discreet. To be honest i was thinking a vertical for HF for the time being might need to suffice as its easy and quick to get up. For now i will only be listening but have the US exam notes for technicians license and hoe to be off and running soon. Do you know who i would need to speak to about the precise laws / restrictions etc? I presume the planning dept in local

government? Having come to the US with visions of the huge antenna farms we Brits can only dream of it would be just my luck that i cant even get up a simple wire! Back home i just about managed to squeeze in a half size G5RV so i would be nice to get something i can use on 80m.

Now i need to get time to get my head down for study.

Best wishes

Andy

Too late David
But I have a question for you, Does the New World (Rumsfield) use
the term "equilibrium" in any of the engineering curriculums or are
you quoting what appears to be American English and not that of the
Olde World? Personaly if I was dealing with entropy or those wonderful
graphic steam tables +equilibrium" would be discarded in favor of
yours. But to explain all that stuff would be impossible with this
group so I opted for the Universal term that was current in Newton and
Maxwell time. Maybe what we are seeing is a intrusion of new math
into physics! Either way it does explain to me why american jaws
dropped in ignorance when the term was used.

Interesting! And from the verbiage -

"The Yagi antenna has a plethora of detuned elements compared to the
driven element which is always resonant".

Funny, every yagi I've designed and built has a driven element which is
NOT resonant. It has a non-resonant element and a matching network of
one sort or other, which is entirely different than being resonant. And
strangely enough, is high 90's efficient. Which Art claims isn't possible.

Ok, so this would mean that at every north or south latitude the angle would be different, and at the equator would be zero, since there's no coriolis effect there. Please give a table that shows the tip angle versus latitude. (Bet you won't because it's secret) And at the north or south pole it's not definable so antennas can't work there..

Why haven't you mentioned these facts before? Bet you haven't because you didn't think of it, but you'll claim otherwise or just not respond.

Actually it does, but it takes something like the gravity of a star to
become noticable.

Yup. I brought a 10m dipole closer to resonance on 20m by using a clip lead
to attach one element to an eight-foot ladder that was laying in the dirt.
The tuner was able to match this mess and I had a 2000 mile QSO with 100w.

Might have been some feedline radiation in play.

Sal

Archive-name: radio/ham-radio/moderated/crossposting
Revision: 1.1 2009/04/12 19:42:04
Posting-Frequency: posted monthly
URL: http://www.panix.com/~rram/usenet/rram/index.html

Changes followed by "|".

After a 30-day public discussion and feedback period to gauge reader
opinions in March of 2009:

http://groups.google.com/group/rec.radio.amateur.moderated/browse_thread/thread/d7d337db35
f23326

the rec.radio.amateur.moderated Moderation Team has decided to consider
amending its charter, and permit limited simultaneous crossposting to
rec.radio.amateur.moderated and one other unmoderated
amateur-radio-related discussion newsgroup. We are currently trying
this on a temporary basis (90 days, through early July 2009), and adopt
it permanently if successful.

Approved rec.radio.amateur.* newsgroups are those that are currently
listed in the latest version of the "List of Big Eight Newsgroups" which
is crossposted monthly to news.announce.newgroups, news.groups, and
news.lists.misc.

Approved alt.radio.amateur.* and alt.ham-radio.* newsgroups are those
that have been created consistent with the suggestions in "So You Want
to Create an Alt Newsgroup" at:

http://www.faqs.org/faqs/alt-creation-guide/

Approved regional hierarchy newsgroups are those that contain either
"radio.amateur" or "ham-radio" in their names, including
uk.radio.amateur and aus.radio.amateur.misc.

We will make every reasonable effort to keep our list of approved
newsgroups up-to-date. In case we have overlooked any, and a submission
is rejected in error as a result, the rejected submitter can E-mail us
at our administrative contact address (in the signature at the bottom of
this article, and the default Reply-To for the rejection message)
requesting that it be added, and that the article be approved. We may
still choose to reject articles crossposted to any alt.* newsgroup with
an inappropriate name, including obscene language, embedded
name-calling, or encouragement of unlawful conduct.
```

Please direct any comments, questions, or criticisms to
rec-radio-amateur-moderated-request@panix.com.

Huh? I can tune across the frequency range of a Yagi-Uda antenna,
measure the VSWR, and most certainly see a resonance dip at the design
center frequency. I can also attach a grid dip meter to the feed,
through a coupling loop, and see the resonance. Take away the
reflector and directors, and we're left with an ordinary dipole, which
is most certainly a resonant antenna. If the driven element is not
resonant, what is producing the dip in VSWR at the design frequency?

Goggling for added support:

Close. It's like Kirchoff's Current Law. The sum of all comments
over a point on Usenet is zero.

<http://802.11junk.com/jeffl/crud/11-655899.pdf>
Figure 3B on your patent application indicates:
Computer Derived Performance
(Use NEC, Mininec, or Mathcad style program)
along with some gain, F/B, and Z computation results. Above that is
part of a coordinate input table, showing wires 21 thru 23, used to
define antennas in a variety of NEC2 modeling programs. That suggests
that you have created an NEC2 (or NEC4) model for your Gaussian
Radiative Cluster (Antenna). This would be a big help in
understanding your antenna. I especially want to see how the elements
can be random and resonant at the same time, and what degree of
randomness is required.

Jeff, Art,

What bothered me is that if an antenna is really made from random elements, I can't quite figure out who designed it? G-D? The ether bunnies? No one? Is it a karmic joining of the forces of the universe? The work of the devil?

If it is a fixed number (or limited set) of elements placed in position, then it is certainly not random.

I am not an expert on patents, but from what I do know, if you can't patent randomly placing elements in no pattern. If you place them in a pattern, it is no longer random and can be patented if you can define that pattern.

You could observe, measure or calculate that if you randomly place elements, one or more of the resulting patterns, layouts, etc will produce specific results and patent that specific pattern. There is no requirment that you invent something by any means more scientific than just throwning sticks on the floor randomly.

However if you can not identify that pattern, you can't patent it. If you do identify that pattern, you can patent an Unwin antenna, or a Liebermann-Unwin antenna, if Jeff were to find that critical piece you were missing.

I did not read the entire patent application, Jeff posted it what was very late last night for me, but I did browse it. If the antenna is a modified Yagi-Uda design, then it is a design and not random. If it just happens to work better than one, I'm not sure that is relevant to the patent.

I think that what you are trying to patent is randomly tossing metal sticks on the ground and connecting wires to some of them in some random fashion. I don't think this is what you had intended to do at all.

Geoff.

That's not resonance, it's matched at that frequency.

> reflector and directors, and we're left with an ordinary dipole, which
> is most certainly a resonant antenna. If the driven element is not

The match. It's normally not a resonant element when in the middle of a
Yagi-Uda array, although it's _near_ resonance when the rest of the
elements are removed.

It is possible to have a resonance at the match frequency, but unusual.
Run a couple yagis through Eznec and check the driven element impedence.
For instance, the NBS yagi that comes with Eznec. At 50.125 it's
11.7+j5.9, not very resonant. I have a 222 yagi that has a DE longer
than the reflector, also unusual, but it works fine.

The first object is to establish equilibrium by using a WL radiator. Anything less breaks away from equilibrium.Adding a second radiator affects the electrical length of both radiators together with their angle with respect to each other i.e. not planar.
The question then becomes what is the reference line to determine the exact position?
Now you can deviate from such a equilibrium by adding a radiator that is not a WL which then pressures the arbitrary boundary close to rupture and so on. Thus the available number and electrical WL escalate each without a reference point expands because it will change as you move it on the surface of the Earth. Thus "random" is a hard word to use when it is any arrangement that satisfies the term of equilibrium. If the radiators were magnetic in nature and was thrown on the floor they could combine in a arrangement via repell and attract that would be maintained or jarred to another cluster position while still retaining equilibrium. Thus one should see how difficult it is quantasize an arrangement when equilibrium has no measurable point of reference that meets PTO requirements. But I would be interested if a solution could be presented that provided the metrics of such a arrangement such that a drawing could be made that is a picture of any final arrangement of the cluster that would occur for all to duplicate. It was for the above reasons why I included a typical computerized arrangement which by itself is not required in a patent request. As always the difficulty is in the details thus the need to establish a datum line which I can use for the remaining disclosures is required such that it is not rejected on technicalities while providing all details in advance to the World. Thus we have what Jeff said, The sum of all comments on this new group amount to zero" duplicate under any circumstances.

The patent application requires references to prior art. How far one
goes back is strictly up to the applicant. If one wants to go back to
the creation of the universe, it's probably acceptable.

>G-D? The ether bunnies? No one?

Actually, it is possible to patent something that requires randomness.
I did some patent searching and found something on the topic. 4
example:
"Random antenna array interferometer for radio location"
<http://www.google.com/patents/about?id=yip4AAAAEBAJ&dq=random+antenna>
However, my reading of Art's application shows that the proposed
antenna is not really random, as it would fail any test for the degree
of randomness, mostly because the method of achieving random element
lengths is not specified. For example, the range of acceptably random
element lengths is missing, as is the effects on the basic parameters
(gain, F/B, VSWR, etc).
<http://en.wikipedia.org/wiki/Randomness_tests>
In my never humble opinion, the term "arbitrary" would be more
appropriate, as it does not require such a test and is not constrained
by any real or imaginary limits. Unfortunately, an arbitrary design
is not patentable.

>Is it a karmic joining of the forces of the universe? The work of the devil?

I don't know, and don't care. While some of my antennas require
divine inspiration during the design phase, and divine intervention
during testing, one would hope that Art would supply sufficient
information in the patent application to remove any need for such
outside assistance.

>If it is a fixed number (or limited set) of elements placed in position,
>then it is certainly not random.

Substitute arbitrary for random and see if the description works any
better.

Incidentally, it appears that not everything is random.
<http://802.11junk.com/jeffl/crud/11-655899.pdf>
See background [0015] which proclaims:
"... where elements 22 through 24 are made of aluminum
rods of one inch in diameter."
Well, "one inch" doesn't sound particularly random. Does it only work
with this diameter? Does it need to be solid rod, or can it be
tubing? What's this monster going to weigh on top band? What
happened to elements 1 through 21?

>I am not an expert on patents, but from what I do know, if you can't patent
>randomly placing elements in no pattern. If you place them in a pattern, it

Yep.

>elements, one or more of the resulting patterns, layouts, etc will
>produce specific results and patent that specific pattern. There is no
>requirment that you invent something by any means more scientific than
>just throwning sticks on the floor randomly.

Yep. I'll leave the question of how one achieves resonance and
randomness simultaneously as an exercise for the reader.

>However if you can not identify that pattern, you can't patent it. If
>you do identify that pattern, you can patent an Unwin antenna, or a
>Liebermann-Unwin antenna, if Jeff were to find that critical piece you
>were missing.

There's more than one piece missing. I suggested that Art look at a
finished antenna patent for the missing parts and pieces. However,
I'm sure the USPTO examiner will supply a shopping list, so there's no
need for me to do the same. Although there are no patents with my
name attached, I've helped craft about 3 patents. The problems I ran
into were excessively broad claims, and insufficiently specific
descriptions and claims. It turned out to be a rather difficult
exercise, but eventually was accepted. Art's patent application has
both these problems. In this case, random is excessively broad, while
if they interpret it as arbitrary, it's insufficiently specific.

I'll see if I can get the application scanned so that the PDF text is
searchable. Then, I'll run a grammar chequer on it.

>I did not read the entire patent application, Jeff posted it what was very
>late last night for me, but I did browse it. If the antenna is a modified

Antennas are best designed under cover of darkness. However, testing
should be done when the sun is shining or you might fall off the roof.

>I think that what you are trying to patent is randomly tossing metal
>sticks on the ground and connecting wires to some of them in some random
>fashion. I don't think this is what you had intended to do at all.

Yep.

Nothing wrong with this patent application except that granting it
would give Art rights to every antenna made. An antenna with randomly
placed elements could be defined as almost anything. In other words
the patent application lacks UNIQUENESS.

I disgree. If you place element(s) deliberately, they are not placed randomly. It may appear random, for example a discone made of wire elements for both the disk and the cone, but I assure you they were not placed randomly. Maybe not with much forethought, or any accuracy, but that is still not random.

Even if I were to toss a wire out of my window and let it fall where it may, that is not random. There are some random elements of it's placement (where is Ian Malcom when you need him), but the size, length and type of wire were chosen by me, the window was chosen by me, and I had some control of the direction and force.

Seemingly random, arbitrary, etc seem more appropriate than random.

Geoff.

Guys you are forgeting that it meets the metric of equi;ibrium thus
the arrangements that are random are only acceptable if they meet the
uniqueness (see above) of being in equilibrium.
I am glad that others see the difficulty I have been placed even tho
the method of equilibrium has been shown that is repeatable for others
to follow.The examiner has supplied some claims that he sees as
acceptable but as he is foreign born, his thoughts, as with mine, may

not hold up to challengein the U.S. In all other countries intent is acceptable as law is based on the intent of the lawwhen made. In the US the problem is way different where the intent is established by the words the intent of which depend on the times and the envinment which is why there is a need for more lawyers than any where else.
A case in point
"Abortion"
that can be struck down at any point dependent on the grammatical inference drawn by a majority of justices at any given time and how the challenge is posed. Or the environment
where a trial is to be heard and the impact of the dominant race or religeon (Simpson)
Yes, justice can be very blind.

Jeff, as a past examiner you surprize me. Present day patent provide
an immense announ of false hood as one cannot judge what works or not
with the exception of perpetual motion.
There fore isnt it just the claims that count as long as information
is provided in the body
to justify it. I could claim in the body that an antenna described
requires only a small battery to work the world and use that in the
claim. Whether it is true or not cannot be determined by the examiner
and the inventor does not now need to present a sample.
It is for the next inventer to claim a better mousetrap for economical
reasons that he sees where others think it has no valueand not worth
the effort. The initial inventor can lose all if he does not commence
with a commercial effort as ordained by the PTO
No wonder the courts want to limit their involvement in patent cases
and why the rules were changes i.e. PTO being challenged by those who
preside over justice in cases that are challenged. It is for this very

reason that laws in other countries establish the intent of the law AT THAT TIME so a judge presides only with the case at hand and not challenge the political made laws .

Then I would have said "place in a position of equilibrium" and not used
the word random at all. There is a very big difference between random
and equilibrium. If something is placed randomly, e.g. dropped on the floor,
and moves to a position of equilibrium it is no longer randomly placed.

> I am glad that others see the difficulty I have been placed even tho
> the method of equilibrium has been shown that is repeatable for others
> to follow.

That sentence alone disputes your claim of randomness. If a system can be
set up in equilibrium in a repeatable method, then there is no randomness
in the system. There may be more than one optimal point, but that is not
the same as a random one.

Are you trying to patent the device, i.e. an antenna consisiting of elements
in equilibrium, or a method of placing elements in as seemingly random way
to achieve equilibrium?

> The examiner has supplied some claims that he sees as
> acceptable but as he is foreign born, his thoughts, as with mine, may
> not hold up to challenge in the U.S.

That's how I found out that choosing a patent agent who charged us $3500
to write patent applications and then $3500 to chalenge a rejection was
worthless because in the end we did not get the patents. If we had
hired the "best in the country" at $600 an hour, we would of had our
patents.

Now we have nothing except rejected applications which while they bear our
names, they do not have the name of the patent agent we hired on them at all.

No, that is why there are courts. Almost every country has them.

Geoff.

Could be, but in this case there are three degrees of freedom for
placement where only the
cluster as a whole meets equilibrium are those that are acceptable
under the claims.
For descriptive purposes those familiar with the art or even physics
would accept almost anything as long as the entirety is considered in
equilibrium. Remember that after one element is placed in position at
any random place or angle then other added must follow in kind
dependent on how many elements are added even tho the first two
element placed meets all the requirement for commercials. Never the
less, one can choose to include any number of element to be used where
the addition of one immediately changes the position of others
including length to remain in equilibrium. So as I stated before there
is no datum to fix upon so that metrics can be applied. In any othe
Country a cluster of elements which in their entirety are in a state
of equilibrium is acceptable. As seen by prior posts on this newsgroup
"equilibrium" provides confusion in the U.S. and was the subject of
many years of auguement But for those familiar with the state of the

art would see no problem.
and it is they that all patents are addressed to.

That's were having an expert write your patent matters. Depending upon how the application was written, such a claim could leave operating it without a battery or with a large battery in the public domain (outside the scope of the patent), and so on. Claims like that are best left to advertising and not patents.

> It is for the next inventer to claim a better mousetrap for economical
> reasons that he sees where others think it has no valueand not worth
> the effort. The initial inventor can lose all if he does not commence
> with a commercial effort as ordained by the PTO

No, the inventor is not required to do anything with their patent. You can sit on it for the rest of its life and do nothing. You are assuming that one has to sell something to pay the mantainance fees. The total paid out in parts at 3.5, 7.5 and 11.5 years is under $4,000 for a small inventor or company. That's $266 a year over 15 years, the approximate life of a patent that takes 5 years from first invention/publication to approval.

I'm sorry that patent bombing is no longer a poor man's game. (filing lots of patent applications and hoping one will pay off). However the rules of the game changed, possibly for the better. If you are quick about it, you can file a provisional patent and shop it around for the money to make a real patent out of it, or sell it to professional investors.

Since the filing fee for a small inventor is $110, you can file one for the cost in the US of dinner, a movie and a baby sitter.

The downside is if you fail to file, or fail to convert the provisional patent into a real one before the year is out, you loose, as I did with several inventions I wrote provisional patent applications from my blog postings but was unable to file them.

The courts want to get out of it because it is a lose-lose situation for everyone. If there were to be binding arbritation by experts, or just licensing deals, everyone would be happy.

Lets say you toss a bunch of metal rods up in the air and let them
fall randomly, the odds of them falling in the shape of a yagi is the
same as falling in any other position. While it is extremely unlikely
they will take the pattern of a useful Yagi antenna it is also just as
extremely unlikely that they will take any other pattern.

In your case there are a number of variables with that could be
predetermined, however all it takes is one variable chosen by chance
to make it random.

Arthur could help by defining randomness limiting it to positions
within a certain set as is done with gaming equipment. There are also
a few other words he also needs to define as they appear to have a
rather unique usage.

Jimmie

there is no 'equilibrium' used in the electromagnetics texts in my
collection that i can find. 'steady state' is the closest, but that is
normally used to refer to the response of a system after the transient
response has died out. 'equilibrium' is often used in thermodynamics, but
any analogy to that in electromagnetics is useless as it refers to a state
where there is no energy flow, and if energy isn't flowing then you have no
radiation. 'equilibrium' could also refer to a mechanical system that has
reached 'steady state' or a stable state, but again similar to the
thermodynamic use it is useless for electromagnetics... maybe for
electrostatic or static magnetic fields, but not for radiation.

Thanks for the response David. I will have to look at my books
regarding basic laws which are all connected to Maxwell's laws. A case
in point is the tank circuit which is seen as being in equilibrium and
where there is current flow and which I state is the electrical
circuit for radiation that is totally in accordance with the laws of
Maxwell. If you agree it can be used for a electrostatic field then
you are agreeing to any circuit which contains a capacitor with its
own contained electrostatic field. I agree that the term is not
presently in the books
which is why progress has been stunted and the reason for my
disclosure but I assure you that this is an error of the education
system since equilibrium is the basic datum line for all laws
including electrical. As an over check on my position antenna programs
will always
point to a non planar form in equilibrium per Maxwells laws so with
the assumption that programmers did use Maxwell's equations correctly

then my findings have been confirmed
Hang on for a while and I will report back on my findings as well as
Wilkedia type of definitions. Since the Universe is considered to have
an electrical foundation which includes the four forces of the
standard model then without the Universe
achieving a point of equilibrium we can all be seen as traveling thru
the Universe at the speed of light with no end to motion to place us
in a state of balance, a terrible thought if we cannot rely on seeing
the sunrise every day.
Regards
Art

Geoff, as you are aware I have many patents, both under the GE banner
as well as my own. The advantage of being an independent inventor or
private entity is that the Patent Office is committed to assist. To me
this is an advantage that exceeds paying $10,000 to a patent attorney.
In addition, when having a patent attorney he may well not advise you
as to what is happening between he and the PTO, and you as the
inventor cannot communicate with the PTO yourself. One time I had to
drive overnight to D.C. to fire my attorney such that I was able to
file something myself with just hours to spare. The costs that you
mentioned are incorrect even for a private entity on all that have
been filed by me but I understand changes have been made with respect
to the timing of maintenance fees e.t.c which appear to muddy up the
water some what. I have provided my credit card number to draw upon
and if they want less then they will tell me, which has been my
standard aproach over the years.I am comfortable with my present
status weather I win or lose as my work is now of record.
Cheers

Jim,
The patent examiner is committed to help me so such things do not
happen.
If you do not have an attorney they will step in and render
assistance.,Remember that It is really a question of presentation to
those skilled in the art of which the examiner is one
and not to the World at large. There is a former examiner in this
group so you really should address such questions to him for
verification that you can trust.

Courts are for applying the law of the land. In the U.S. laws are made
that cannot be enforced in the courts. In the UK the intent of any
initial law must be established and approved by the justices in the
House of Lords before it becomes the law of the land.
If the US Supreme Court did the same thing thousands of lawyers in the
land would be out of a job since the law is the law where intent has
been pre provided such that lawyers have very little work to do Or
even to argue about the intent of the law at hand. This allows for
separation of Church and State so that aparthide does not take place
and democracy is retained. The moment church is not separated a single
church then becomes dominant in the land where its edicts thus reign
supreme, which is a real problem if nearby Countries adopt a different
religion such that conflict reigns and where neither are willing to
abandon their faith to that of the unbelievers.

BTW, this link has to do with resonance of the yagi in a narrowband range just below the director array cutoff frequency, and nothing to do with the driven element.

Google can be your friend, but when used without vetting the results can sometimes lead to embarrassment. In this group, it's nothing like the nonsense spouted by Art and some others however, so no worries.

> Regards
> Art

On a quick google on Newton equilibrium there does appear that
equilibrium is not liked
say as much as "balanced" Thus science is essentially changing laws to
today's intent
and at the same time describing the laws with respect to Earth and not
the Universe.
I can see now where so much reference is to gravity and not the
combination of Gravity
accompanied by the spin action of Corriolis, where neither can exist
without the other in cosmic terms. Thus every action and opposite
action considers the Corriolis as non existant
such that Gravity alone should be part of the Standard Model. It now
can be seen that the
"intent" of the laws has changed over the years without emphasising
the "core" of the laws as intended by the providers. Fortunately NASA
does not have to discover new laws for
each and every part of the Universe since the laws we use are
Universal and not just confined to Earth as we know it. Thus I,
coming from the Olde World, still adheres to the intent of the law in
macro style where others understand it as decifered by the new World
in micro form for a more understandable relationship in todays
education. In other words
first principles in education has given way to continuos plagurism or
learning by rote.

>
> tom
> K0TAR

My goodness. This is the silliest thing I have heard in years.
A yagi has a bandwidth based around a resonant frequency which is the
change over point
around which the impedance is not measured by the resistance alone.
If the feed radiator is devoid of any proximitry effect then its
material length differs from that of an array where the proximetry
actions exists. Thus a yagi driven element is resonant and different
from a driven element alone because of the proximitry effect. If your
radiator impedance is 11.7 +j5.9 then you are not at the point of
resonance which must be solely resistive. Modify the proximetry effect
to make it resonant.
This is exactly what you did by using a short length reflector at a
abnormal distance from the driven element. Methinks you regard only 50
ohms as being resonant where anything different from that is not
resonant. Tom you are nuts!

On what planet did you find this patent examiner? When I was trying
to help scribble some patent applications (in about 2000), I never was
able to communicate with any patent examiner. They're totally
isolated from the applicant to protect against intimidation and
bribery. I received a check sheet and a letter of explanation of what
needed correcting. Attached was a list of recommendations and a
schedule for resubmission. The first one required 5 resubmissions,
over a period of about 2 years to get through. The next two were
somewhat easier and only took about a year. I was about to give up on
the last two, when the company hired a patent attorney, who got things
rolling again.
<http://en.wikipedia.org/wiki/Patent_examiner>

Sigh:
<http://usptoexaminers.com>
You might want to see how your examiner rates.

>If you do not have an attorney they will step in and render
>assistance.,

Who will? Certainly not the examiner.

The USPTO has the "Inventors Assistance Center" to help individuals
with their documentation:
<http://www.uspto.gov/web/offices/pac/dapp/pacmain.html>
The problem is that they can only help with the process, not with the
merits of the individual patent. You can talk with someone in
customer service, but that's the same story. If you want help with
your claims, you'll get directed to a patent attorney.

>Remember that It is really a question of presentation to

Agreed. Experience is good substitute for guesswork and Googleing.
Incidentally, I did a Google Groups search for "former patent
examiner" in this newsgroup and found nothing.

Right. One does NOT need to demonstrate that something works in order
to obtain a patent. There are plenty of patents for some
non-functional devices. Basically, it needs to be novel, non-obvious,
and provide a useful function. That's all.

Rubbish. However, I think I now understand your writing style. Most
of your sentences are comma splices or conjunction splices, which glue
two marginally related concepts together. This lets you slide neatly
and gracefully from one topic to the next, usually in one paragraph.
Were this done without the splicing, it would appear as an abrupt
change in topic, or just random thoughts. Impressive. I need to
learn how to do that as it appears to be quite useful. Thanks.

Argh. I just checked my billing log (Quickbooks). The first one took
over 3 years. The other two about 2 years. My problem was that I
didn't get paid until AFTER the patent was accepted. Remind me to
never accept a contract like that again.

WW 2.0 started on Sept 1, when Germany invaded Poland.
<http://en.wikipedia.org/wiki/Invasion_of_Poland_(1939)>
It took England and France 3 days to decide what to do next. They
eventually declared war, then did nothing through the phoney war until
May 10, 1940, when Germany reminded them that they were at war by
invading the Benelux countries.
<http://en.wikipedia.org/wiki/Phoney_war>

Are you sure you really want to celebrate Sept 3? It seems more like
a national embarassement than something to celebrate.

First of all, this is completely 'off-topic'.

Then I think that anyone who 'celebrates' the outbreak
of war should have his brain re-aligned.

> It seems more like a national embarassement
> than something to celebrate.
Furthermore, in light of recent history, Americans
would do well to use the phrase 'national embarrassment'
with extreme caution or not at all.

Moreover, embarrassment is spelled with two 'r's.

Corriolis deals with mass, so it is incorporated with the same core Math
that deals with Gravity, Inertia, Acceleration. Corriolis really isn't a
"force".

However, since you bring up the idea of "spin", it seems to have become more
important than the laws of Physics in some classrooms.

> Regards
> Art

On a quick google on Newton equilibrium there does appear that
equilibrium is not liked
say as much as "balanced" Thus science is essentially changing laws to
today's intent
and at the same time describing the laws with respect to Earth and not
the Universe.
I can see now where so much reference is to gravity and not the
combination of Gravity
accompanied by the spin action of Corriolis, where neither can exist
without the other in cosmic terms. Thus every action and opposite
action considers the Corriolis as non existant
such that Gravity alone should be part of the Standard Model. It now
can be seen that the
"intent" of the laws has changed over the years without emphasising
the "core" of the laws as intended by the providers. Fortunately NASA
does not have to discover new laws for
each and every part of the Universe since the laws we use are
Universal and not just confined to Earth as we know it. Thus I,
coming from the Olde World, still adheres to the intent of the law in
macro style where others understand it as decifered by the new World
in micro form for a more understandable relationship in todays
education. In other words

first principles in education has given way to continuos plagurism or learning by rote.

Yes. I know what hate is. I was in East London when the Stern Gang
terrorists were setting of bombs atcivilians at the end of the war!.
As well as when the Hotel King George was blown up by terrorists with
the loss of life.
I was also an evacuee . Same as the two train loads of children that
fled from Europe to the London when Jewish families could not bring
themselves to flee and leave their wealth
I am quite proud of the U.K and the Commonwealth. They took the lead.
It is so easy after the fact to point fingers and say I am better than
you. I also read the J'lem news daily wnere hate is being spread thru
out the World to this very day.Why do they hate Amnerica so much? Who
is without sin today?
Surely Jeff you are better than that. Yes the "phony war" did entice
people and children to go back to their homes in East London only to
die when the bombing started,
But England stood proud.

Hmmm... as I recall, most of the Stern Gang (LEHI) activities were in
then Palestine and Egypt:
<http://en.wikipedia.org/wiki/Lehi_(group)>
I don't see any references to any bombing in London.

>As well as when the Hotel King George was blown up by terrorists with
>the loss of life.

Google doesn't show anything that refers to a King George Hotel
bombing. Perhaps you mean the Kind David Hotel in Israel in 1946?
<http://en.wikipedia.org/wiki/King_David_Hotel>

>I was also an evacuee . Same as the two train loads of children that
>fled from Europe to the London when Jewish families could not bring
>themselves to flee and leave their wealth

They were not allowed to leave. My parents spent most of the war in
various Polish concentration camps. By the late 1930's, most of the
alleged Jewish wealth had already been confiscated by Hitler. Poland
had barely recovered from WWI and the 1929 Depression. Wealthy Poland
is an oxymoron. If my parents could have left, and some country would
have welcomed them, they would not have hesitated.

>I am quite proud of the U.K and the Commonwealth. They took the lead.

After Sept 1, 1939, there were no "leaders" in the west. The number
of changes of government in England and France should offer a clue.
The only leading was done by Stalin, by invading Finland in 1940.

>It is so easy after the fact to point fingers and say I am better than
>you. I also read the J'lem news daily wnere hate is being spread thru
>out the World to this very day.Why do they hate Amnerica so much? Who
>is without sin today?

I'll give you credit for a good imagination, but methinks you're
reading far too much into what little I've said. Israel does not hate
the US. If anything it depends heavily on the US for military and
economic support. There have been some disagreements and incidents,
but in general, the relationship is quite stable.

What I was questioning is that you would celebrate starting a war, as
if this was some kind of event worth emulating and copying. Perhaps

it would be better to celebrate and end, such as Nov 11, 1918 for Armistice Day or VE Day, May 8, 1945 for WW 2.0.

>Surely Jeff you are better than that. Yes the "phony war" did entice
>people and children to go back to their homes in East London only to
>die when the bombing started,

It was 8 month between the invasion of Poland and the invasion of the Benelux countries. How long would you expect the kids to stay evacuated?

>But England stood proud.

True. They endured and then turned around and fought back. Without England, we would probably be speaking German today. There are plenty of other thing England should be proud of, but the muddle at the beginning of WW 2.0 is not one of them.

You may well be correct I thought it was King George before the
Israelis blew it up
and killed all those people.

And you think the U.K. was not broke after all the fighting and the
depression?
The Jewish bankers would not provide a penny to the U.K. in WW1 until
they got the pound of flesh from the UK (Balfour treaty) Yes there has
always been many Jews living in the U.K.

You said I should be embarrassed when for me I feel proud.
You insulted my father who fought in that war and my Uncle who died
You think I should stay quiet while you thro insults?

 Israel does not hate
> the US.
Hmm They hate America even while they get billions.
You should read the Israeli news columns where Jews from around the
World write in
and call for the U.S. to get out of Israeli pockets. Any body around
the World who is against Zionism and writes in is censored. Probably
the same if they write in and mentioned the Stern gang.

 If anything it depends heavily on the US for military and
> economic support. There have been some disagreements and incidents,
> but in general, the relationship is quite stable.

I doubt that, they want us to go to war for them

I didn't count the years, went home and then the V2s and they scared
me came so I went back
total of 5 years plus and four different foster homes. Schooling a
joke

> >But England stood proud.
>
> True. They endured and then turned around and fought back. Without
> England, we would probably be speaking German today. There are plenty

Nobody resisted Hitler all were waiting for some body else. It took
the U.K. to respond
even tho they were dead broke and Germany stopped 22 miles away from
England's shores.
Let us put this behind us. The British are fighting along side us in
the ME and in Afganistan
and you want to belittle them as they die by our side. They don't
deserve these kind of snears and nor do Canada and Australia and the
rest of the Commonwealth.
All I wanted to do was remind all what happened 70 years ago but I
sure did not think that insults would come the way of our allies from
the U.S.

And why not? This is a discussion group. Any one can concur or
challenge
the statement. If I supply the proof of anything then silly attacks
begin
I can handle them but it does not improve on my knoweledge.
I will state right now that overall size or straightness of a radiator
is not
implied in Maxwell's laws in any way. So I would like to know where
that notion came from.
Is that so bad?
So Doctor, what have you got to offer regarding radiator straightness
as a person skilled in the art ?

Well, let's take a look at some yagis from known companies, the US
National Bureau of Standards and some well known hams. This is a small
subset of the yagis I have models for. Almost all are HF or low VHF so
we don't have to get into an argument over proper boom correction
factors. Yes, something else you've never heard of, Art.

Art, you already conceded to an exercise in futility that was a very
good example of a bent antenna in its worst case. You would think you
would have learned your lesson.

Quoting W8JI's web page:
"How do we make a small antenna as efficient as possible?"
"... we make the antenna as large and straight as possible in a line.
We don't fold, bend, zigzag, or curve the antenna especially in the
high current areas."

I don't know what the fuss is all about. Transmission line
currents don't radiate (much) because they are out of phase.

Random folding of an antenna more often than not introduces
transmission line currents into the antenna itself - not
good for radiation purposes.

Transmission line currents cause destructive interference -
that's good for transferring power from one place to another
but not good for radiating RF.

There are certain special-case antennas where folding occurs
without introducing destructive interference, e.g. a 1/2WL
folded dipole or a full-wave quad where the wires are a
large enough percentage of a wavelength apart so they don't
cause near-field destructive interference.

Hint: RF radiation cannot be understood without understanding
constructive and destructive interference in the near, medium,
and far fields.

Cecil, you should know by now that a half wave dipole of any type
couldn't be all that efficient or effective. Art says so.

So how could these possibly work? They aren't "resonant"!

What a horrible situation. They couldn't work, could they?

Enter the matching network. This transforms the awful unusable impedance into something the transmission line can handle. Usually 50 ohms nowadays.

You seem to have a problem with this concept Art.

Go back to school.

It seems that some do not understand what the Corriolis force is so
here goes
When the Big Bang ocurred all energy was in an arbitrary boundary
just like the Sun is. When the forces (four forces of the Standard
model) could not be contained with in the boundary the boundary broke
which as scientists state was the begining of our Universe. Before the
arbitrary boundary broke it is a state of equilibrium (This is also
duplicated by the Sun) You can visualize a ball which contains all
energy by placing vectors all around the inside where for every vector
on the inside there is an equal and opposite on the outside. Tho
energy cannot be created or destroyed, kinetic energy can occur at the
expense of potential energy such that the outside vectors are over
come. The boundary breaks and the excess forces are released until
the boundary is able to return to a state of equilibrium. Now when the
break occurs it is at the point of a particular vector such that the
breakage is created by a shearing action, as the forces in question
was not aligned, with spin. Thus when any energy,particles etc they
escaped with a spin action which force forces to balance requires an
equal and opposite reaction and the Corriolis force is that component.
Without the Corriolis component we could not remain on this Earth and
gravity could not exist. Thus to state spin or torque is not a force
is truly rediculous. Let the insults come.

Cecil
It is not related to volume. It is because they are both closed
circuits thus all radiation
can be accounted for i.e. all the circuit wire contribute to
radiation. Any length less than 1WL does not !
If one introduces lumped loads then you have to cancel them, no
problem. Maxwell clearly stated that we are dealing with distributed
loads only, ie root L.C. The inclusion of volume is only because some
people cling to the magnetic field theory as opposed to the particle
theory. Equilibrium allows for multiple shapes and sizes for
achievement

Heh it is just standard classical physics. Just like saying a tornado
is not a force.
or a antenna cannot be resonant. Totally rediculous. If you want to
know more take a physics lesson maybe more than one in your case. Now
the Electroweak force is only called weak because it is the weakest of
all the initial forces created in the big bang. This
is the force created as a result of two forces acting towards each
other but not on the same plain where a boundary is broken. Plain
Classical Physics, nothing more.

But Tom your previous posts have not contained anything to respond to
unless you want retalatory sniping, but that is a waste of time. As
for no information presented, Einstein died
before Electroweak force was resolved tho he was convinced the answer
was related to radiation. Now I have identified it to you! Surely you
feel good. You now know something
that all the big boys have struggled after. The Electroweak force is
that which propells particles into free space so that it accelerates
in a straight line. In other words "point radiation". This being
similar to eddy current. Einstein concentrated on internal and
external forces without concern to the "hoop stress" that is part and
parcel of all boundaries. Just like that which surround a bubble.
These same two vectors that create a shearing force is equal to the
combination of gravity and the Coriolis force. This is the reason why
a vertical antenna must be tipped to form a isotropic radiation
pattern in equilibrium which computer programs confirm. No, the above
is not printed any where in the College books, but it will.

No information you say? It is just that you can't handle it so you depend on insults.
Yes, you did get information but you have not the grounding to understand what you read.

The British have paid through their noses for that help.
I believe the last payment on the 'Lend-and-lease' act
took place in the late 1980's.
The US also seized the opportunity to establish 'dollar-rule'
and look where that got us!
Then there's the energy waste the US is 'famous' for.

And now some of them speak of 'national embarrassment'....
Sure.....................

But does Art realize that a 1/2-wave dipole is a fractional wavelength radiator that couldn't possibly have his definition of "equilibrium," yet it has the same measured pattern and gain as a 1/2-wave folded dipole?

Yes, that is correct, but the power used on a 1/2 wave dipole is half
that of a full wave.
A closely folded dipole radiates the same as a Quad . View Cebik's
comments on this

A full wave what? Are you calling a folded 1/2-wave dipole a full-wave antenna?

For equal, matched power applied either to a 1/2-wave dipole or to a folded 1/2-wave dipole, and although their feedpoint currents will be different, both configurations will generate the same values of field intensity.

Also how do you explain this, given that the 1/2-wave dipole by your definition does not have "equilibrium?"

The things even skilled observers of this force seem to understand can be even more subtle than at first thought! Most of us tend to 'view' things and 'solve' problems in two dimensions. That person is in my face or I'll just flank attack this, said in humor here. But even a very skilled and observant person, for example, gains a really more interesting perspective of life and everything around them when .. for the first time .. they solo fly an airplane!

The average person takes about six to eight hours of dual instruction to get to the level of awareness at which it is safe for the flight instructor to let the student go it alone. Just before takeoff when at the practicing takeoff and landing routine is going on, just before takeoff, "Well, your good enough at this to do it on your own! Take it around the pattern by yourself!" And the flight instructor pops off his seat belt, opens that right side door of the aircraft in a Cessna 140 or 150, for example. Gets out and slams the door shut and walks away!

The average student is so thrilled and whatever at this he or she just jams in the throttle and away it goes! But then even the most capable candidate suddenly has a different perspective of things when as the get set for their first solo landing. as they are looking down into the whole space between them and the approach end of the runway, it hits!

It's the first time they ever have really had to make a life or death decision in more than two dimensions! Height is totally involved here too. Suddenly, even though they don't realize it, they are dealing with the third level of infinities. You can have an infinite number of points in a line. But since you can have an infinitive number of lines in a plane that means the second order of infinity is so defined! And .. surprise .. you can have in an infinite number of planes in a cube or sphere, so there is, for the first time, life or death, the experience of their total involvement in level three of infinity. Plus since time is the fourth level of infinity, when the wheels touch the pavement and the student completes this once in a life time experience, their life will NEVER be the same again.

For the rest of their life they will begin solving problems and understanding what is said, displayed, posted in a discussion, all by looking down into the scenario. And once this is done, you can NEVER go back again to the person you

were before this event.

And no, computer games and flight simulators don't do it, unless the simulator can kill you if you make a mistake, grin! It has to be the real thing. Every Peregrine Falcon knows when to turn lose in the dive of love, as far as I've ever known, chuckle.

But that also doesn't mean you know everything about force problems to which you are presented, grin! Yes, I was the Chief Flight Instructor for Texas Airmotive Company at Easterwood Airport in College Station, Texas, during much of Viet Nam. And I had to ride at least once with all the Texas Aggies who were trying to become pilots as part of their path into the future of life. Which, incidentally included such people as Robert Barr, one of the pilots for the US Air Force One and what became some 47 US generals. In my humble view all because they jumped forward to multi-dimension problem solving.

But .. that doesn't mean even at this level of perspective you see all that confronts you, grin.

I never realized for more than a decade later, how this issue of Coriolis Force is far more important to all living things than I suspect even many of us here have understood. As, much later at this, the CEO for the manufacturer of Hanover Trailers here in Bryan, Texas, the actual marketing main vector for the introduction of all the gooseneck cattle and small utility trailers in all the USA, I learned lots more, I think. Notice I said, "I think." No, the original gooseneck small utility trailer was originally created by James Batchler of Throckmorton, Texas, in 1936. But even as it vectored out into the Hanover Trailer in the 1940's and mushroomed into tons of other manufacturers, it was the custom horse trailer versions of this which revealed something else to me about Coriolis Force.

Yes, I knew the toilet water runs around the bowl one way on the North side of the Equator up here in the USA. And the other direction down in Australia. But I kept getting asked to build trailers for horse owners for more than two horses with stalls at an angle! The head of the horse was asked to be toward the left side of the trailer. The stall gate was angled back on the right side so the horses were stalled all with their heads forward and to the left! Teir rear ends behind them and to the right. I asked, "Why?" I was told, "It's simple, Mike! A normal horse is right footed. If they go to fall, they always start to put their right front hoof out first to give then the best chance of handling the situation."

Hmmmmmmmmm. Interesting. As a human, do a little research. I think you will find that, just as most humans are right-handed, we tend to start walking or running with our right foot also! Hmmmmmm. Interesting. So I started looking down into the problem and yes, dogs and cats do to! Why? Well, if you peek down into all this, all vertebrates seem to be right sided, I think.

Duhh .. then why? I speculate. Well, if all vertebrate life is somehow related over all these eons, is this because all current life forms sort of focus on evolution on the planet from one side of the Equator? And they swim looking for food kind of right sided so they don't have to fight the average

Coriolis Force against it for the best chance at eating easiest? And so on? And does this really mean that this is really all 'proof' that even the humans came from what was most efficiently evolving in the march of life traveling the the fourth dimension that we need? Even for huge numbers of generations?

And might be even more of an explanation why there is still so much fuss going on between even very brilliant and skilled engineers who may not even ever see the real issues of why things seem to be different between them, or the need to do everything we can to go forward with the least confusion and flanking amongst us all?

For what is going to become of all this Coriolis Force issue, perhaps, on December 21, 2012, and who will be in the right doing what for all us humans and so on at that time?

Chortle!

Mike I agree. A bullet has a three dimensional force so that it can
attain a straight line trajectory, the same that a radiated partical
must have for a straight line trajectory.The bottom line is that every
action has an equal and opposite reaction per Newton which means that
one must turn to the breakaway from equilibrium in the Big Bang. to
determine
the number of forces that are available when one considers what we as
humans must determine as what can be equal and opposite. With in the
earth's boundary we must recognise the existance and the impact of the
Coriolis force in our every day life including the need for spin on a
projectile so that it may attain a straight line trajectory. A space
rocket succumbs to the Coriolis effect by turning slowly while it is
attaining height as well as when it escapes from earths boundary where
it uses centrifugal force or spin. The boundary rules I consider the
greatest reasoning of all to human kind and that is a true picture as
to the laws of Newton.
Radio is in the stage of two dimension the same as the human race when
they stated man was never meant to fly purely because they object to
change of the existing perspectives
as Gallilao found out to his cost among others. If one considers the
std model one knows that the strong force is atom related via
separation which has unlimited energy and yet many blithly believe
that the matrics of a radiator is torn apart to produce radiation.

If this were true, nobody would pick up a microphone or even use a CRT when assuming
the beam particle came from the matrics and not on a particle that came to rest from outside our boundary. It all emphasises that the human race is resistance to change because of the fear it can generate such that they rather not want to know, At the moment true radiation is not fully understood and on this newsgroup they don't want to know unless they can read it in a book in college Are they going to alter radiation computer programs that support the impact of the Coriolis effect or go ahead and still use them despite the so called errors that they supply?
Best regards
Art Unwin KB9MZ xg(UK)

Bullets arc, they don't go in a straight line. A bullet shot straight
and level will hit the ground at the same time as a bullet dropped from
the same height. That describes an arc that is proportional to the
velocity of the bullet.

While we're at it, the coriolis force water down the drain difference
between southern and northern hemisphere is an urban myth. While there
can be some effect on the rotation, frictional and initial conditions
are so much greater that the coriolis effect is measurable, but it isn't
the reason the water is going down a certain way.

> humans must determine as what can be equal and opposite. With in the
> earth's boundary we must recognise the existance and the impact of the

> projectile so that it may attain a straight line trajectory.

Most people believe that the spin on a bullet acts as a Gyroscopic
stabilization. It's not a demonstration of coriolis force. If the bullet
actually were to use the coriolis force, would it not have to be
rotating at a rate equal but opposite? Which of course means that the

rifling on a rifle would need to be opposite between southern and
northern hemispheres, and at the equator would need to have no rifling
at all, or if you used a gun from one of the other hemisphere, the
bullet would have a tendency to either oppose gravity by traveling up,
or would almost immediately slam into the ground.

> A space

We turned, not the rocket.

> Radio is in the stage of two dimension the same as the human race when

> change of the existing perspectives
> as Gallilao found out to his cost among others.

Most folks believe that the coriolis force is applied in instances of
inertia, and not from an identifiable source, so an antenna, which is
radiating a non-accelerating EM radiation with an inertial point of
reference, isn't affected by such.

,
Correct ,but without spin it will tumble thus a spin force must be
exerted by the rifle barrel
as well as the powder charge

>

That is not pertinent to what I have said so I do not want to respond
to that.
Tho I suggest that Einsteins laws of Relativity would shed light on

the matter.
He moved towards relativity because of his failure to determine the
Weak force
when studying radiation.

> We turned, not the rocket.

Einsteins laws of relativity apply to that, ie who and where is the
observer?

What I am saying that the spin applied in the Big Bang is present in
any arbitary boundary
which you wish to make in this Universe. If the boundary encircles
earth then the external forces must equal the internal forces. In the
case of earth the outer forces consists of both gravity and the
Coriolis force the latter being one of spin.One cannot survive in this
Universe without the other. Thus if you zoom in to a smaller boundary
there must always be a component (vector) of shear (spin) inside that
smaller boundary
to neutralize the Coriolis force per the laws of Newton. If one wishes
to draw a boundary around a accelerating charge as in radiation then
again one must apply both a straight vector and one of spin. This is
exactly the boundary case when a particle at rest on a diamagnetic
surface for the acceleration of charge which are consistent with the
vectors outside the boundary otherwise equilibrium is not in place.

that's enough... the rest is just more blabbering. first, spell it right,
its Coriolis with one r.
next, its not even a 'real' force, and is often called the Coriolis 'effect'
instead of force to make that clear. and it is not linked to gravity, its
linked to rotation. if the earth or any other body didn't rotate there
would be no Coriolis effect on it's surface and it would still have gravity.
I'm not even going to try to address the electro-weak babble, that is
totally non-sequitar.

Well Dr Cohen (chip) gave up in trying educate the psuedo experts of
his findings because
this group was not interested in change. So he took of and started a
company, obtained contracts from the military and is making money.
Crazy like a fox I would say. Same went
with a lot of experts who were driven away from this group in the
past. For me I am having a great time putting the so called experts on
stage so the world can judge their contents.

The unseen readers are laughing at your ignorance. And mine. And almost everyone else's on this list. Because we don't know kaka despite education and experience.

Yep, he's a hoot. Doesn't understand a whit about what he says, but boy can he say it.

I hope someone is keeping a record of what he's saying so that it can be analyzed and turned into a babblegaff generator.

A real isotropic radiator may not exist, but one can get fairly close.
If you believe the model, the total error is 0.44 db. See:
<http://802.11junk.com/jeffl/antennas/isotropic/index.html>
The NEC2 deck is under the photo labeled "main".

I once built one of these antennas on roughly 444MHz out of cardboard
and magnet wire. The oscillator was a small crystal can oscillator
running from a 9V battery to avoid having the feed coax wrecking the
pattern. The impedance was nowhere near 50 ohms and required a bit of
matching to get the VSWR down. I'm now digging for the photos.

I used a piece of string to maintain a constant radius, a tiny pickup
loop at the end of a length of coax cable running inline with the
string, and eventually going to my antique HP spectrum analyzer. On
the 2dB/div scale, it was a fairly good approximation of an isotropic
radiator with errors mostly caused by indoor reflections and
interference with the bench.

You cannot assume that one who makes an accusation has the status of
education to match his veracity. The person who stated that it is an
impossibility does not even posses a high school diploma. Climbing on
the back of his statements puts you back on the stage again!

Thanks, but the design is not mine. I think it came with a 4NEC2 samples collection, MiniNEC, or possibly with one of the other antenna modeling packages. I've got them all muddled together so I can't easily determine the source. I don't think I made any changes to the model. Mostly, all I did was package the results into something presentable on a web page. (Note: I tried to convince Ari to add a web page creation feature to 4NEC2, but failed).

Incidentally, I has some illusion of using the isotropic approximation antenna as a gain reference antenna. I know there are other reference antenna designs that are more suitable, but I thought it would be an interesting exercise. I also built one for 2.4GHz, which was a total failure.

Drivel: Isotropic antenna patents:

"Spherical antennas having isotropic radiation patterns"
<http://www.google.com/patents?id=--I2AAAAEBAJ>

"Isotropic antenna system and notebook computer"
<http://www.google.com/patents/about?id=M2UOAAAAEBAJ>
Using multiple antennas to get a reasonably hemispherical pattern on a laptop.

"Omnidirectional isotropic antenna"
<http://www.google.com/patents?id=VQcYAAAAEBAJ>
Uses a microwave lens fed by wavguide. Pattern is roughly hemispherical.

"Near-isotropic low-profile microstrip radiator especially suited for use as mobile vehicle antenna"
<http://www.google.com/patents?id=wNE5AAAAEBAJ>

"Near isotropic circularly polarized antenna"
<http://www.google.com/patents?id=saMgAAAAEBAJ>

etc.... plenty more found with a search for "isotropic antenna". Of course, isotropic antennas don't really exist. Therefore all the patents must be science fiction.

Incidentally, I'm still scratching my rapidly depilating head about your answers to my question about antenna resonance. However, I wanna do some more reading before demonstrating my ignorance on the subject and making a fool of myself. Real-soon-now.

vertical? The likely results do not fit my idea of isotropic.

"An isotropic radiator is a theoretical point source of waves which exhibits
the same magnitude or properties when measured in all directions".
The only way to make the real point source is the proper tipping. Of course
it must be a monopole.

I forgot to connect my comments to the original question. Sorry(tm).
You're correct. There's no way to get a good isotropic radiator
pattern with a simple vertical radiator. However, you can still get
fairly close if you make the antenna sufficiently small relative to
the operating wavelength. As the physical antenna size approaches a
point radiator, the pattern starts to look rather spherical.
Unfortunately, the gain drops, efficiency drops, and feed point
impedance drops, resulting in a rather inferior antenna.

There's also a question of how close to perfection does the spherical
pattern need to become? Within 0.1dB, 1dB, 3dB, etc???? Offhand, I
would guess anything within a few dB of spherical could be considered
isotropic, as in all the patents I noted.

You're welcome and I agree with 95% of what W8JI says.
(For instance, he is mistaken about the delay through
a 100T, 10TPI, 2" diameter 75m loading coil.)

Some may or may not understand why random folding
of antenna radiators tends to change the radiating
conductors into non-radiating conductors. (The same
effect is at work in loading coils.)

When two conductors are carrying differential coherent
currents with no common-mode current, there is negligible
radiation when the two conductors are parallel to
each other and the spacing is a very small fraction of
a wavelength. It's called a transmission line and most
of the losses at HF are I^2*R. Usually, one of the goals
of a transmission line is not to radiate. Transmission line
fields tend to cancel in the near field due to destructive
interference.

A single straight wire in free space is a very efficient
radiator because interference occurs mostly in the far
field. Fold it back upon itself and unless the
second conductor is positioned perfectly, there will exist
differential currents between the two conductors which
will tend to cancel the radiation - leaving mostly I^2*R
losses at HF.

Small folded/loaded antennas tend to cancel the radiating
fields. The only other avenue for a lot of the energy is
conversion to heat.

> Yes, that is correct, but the power used on a 1/2 wave dipole
> is half that of a full wave.

On the chance that you meant a full-wave dipole in your quote above, I did a quick comparison of one with a 1/2-wave dipole (linked below).

The peak, intrinsic gain of the full-wave is about 1.6 dB greater than the 1/2-wave -- which is due to the narrower lobe it produces. This has nothing to do with "equilibrium."

The 2,082 -j583 ohm input Z of the full-wave version is not user friendly. But if zero-loss matching networks are used at the feedpoint of both antennas, then for EQUAL applied power to each, the peak field intensity produced by the full-wave dipole would be about 1.6 dB (20%) greater than from the 1/2-wave version.

If the power applied to the full wave dipole was 1.6 dB less than applied to the 1/2-wave dipole, then their measured peak fields would be identical. But that is not a power reduction of one half (3 dB), as in your statement, Art.

Increase the length of the one wavelength dipole to a
1.25WL EDZ and the maximum gain indeed does increase by
~3dB over a 1/2WL dipole. Consider that the highest gain
for a single-wire antenna with a figure-8 radiation pattern
occurs with a feedpoint impedance of ~175-j1000 ohms, i.e.
the antenna wire, by itself, is *non-resonant*. A parasitic
element 1.25WL long would have a negligible effect on an
antenna system. :-0

Consider that if one disconnects the feedline from a 1/2WL
center-fed dipole, the two remaining 1/4WL wires separated
by an insulator are *non-resonant*. Breaking guy wires into
1/4WL separated by insulators is one way of avoiding
resonance. :-)

Michael Coslo wrote:
> Any relation to the loosely wrapped "coils" of shortened verticals like
> bug catchers?

Take a look at the geometry. Assuming that the current on one
side of a turn on the coil is equal to the current on the
opposite side of the coil but traveling in the opposite direction,
one can see why those two currents per turn resemble transmission
line currents (differential) rather than antenna currents (common-
mode). (A 10" coil wound with 1/2WL of wire radiates roughly the
same amount of energy as a 10" straight wire.)

Physically large air-core loading coils can be modeled as a
transmission line with a Z0 and VF (delay).

http://hamwaves.com/antennas/inductance.html

The delay through the coil can be calculated by knowing the
Beta = _____ rad/m "Axial propagation factor of n=0 sheath
helix waveguide mode at the design frequency"

The VF of W8JI's 100T, 10TPI, 2" dia test coil calculates
out to be ~0.03 resulting in a ~25 nS (~37 deg) delay
through the coil at 4 MHz.

Drum roll........

From the department of everything you knew about physics is wrong
department......

The Coriolis effect upon RF radiation has some interesting other
ramifications.
Since Coriolis affects radio waves, it follows that gravity also affects
radio waves. This bring up a new and much simplified explanation for
radio propagation. As the RF spins away from the antenna, the coriolis
effect and gravity eventually pull the signal back to earth far away
from the originating point. I always thought that that silly stuff about
atmospheric layers and ionization was kind of dum anyhow.

Each time the RF hits the earth, a new point of reference is made, and
the signal bounces up with a new twist to it.

We're still working on why UHF + signals don't do this. Maybe their
twist is going the other way, so instead of coming back down, they spin
upwards never to be seen again.

Hi OM,

Demonstrate is not possible. The antenna radiation is not correctly
described.

Consider: a commercial AM quarterwave, vertical antenna is probably
95% to 99% efficient. To have an incredible efficiency would add only
4% more to a very simple design that has been around for 100 years.

+0.2dB or less is not incredible efficiency.

You cannot hear 0.2dB difference in sound, you cannot measure 0.2dB RF
difference except with great difficulty.

That doesn't sound right. The directivity gain of an infinitesimal electric doublet (i.e. a dipole with infinitesimal length) is about 0.4 dB less than that of a half-wave dipole. Its similar lemniscate-of-rotation radiation pattern results from the symmetry about its axis. The results for monopoles derived from these forms of dipole won't be too different. It is rather obvious that a receiving dipole of any polarisation won't receive much signal from the end of a transmitting dipole or monopole, however it's oriented - there's no apparent length over which unopposed current is flowing so there's no 'moment' in that direction.

One solution to spherical radiation is the Lindenblad array (and variants that others have chosen to re-name) which presents finite resolved components of the lengths of some of its dipoles in all directions ... but the tilt of the elements has nothing at all to do with Art Unwin's 'theory', it's simply a matter of making sure there's a resolved component in each direction. Of course, a Lindenblad designed for a near-omni pattern achieves this in respect of circular polarisation so it would be ineffiecient in a system where a linearly polarised antenna is used at the other end of the link.

I was once told a true isotropic radiator would have to be circularly polarised because it would be so small that it could contain nothing with a defined axis of symmetry ... that is, the antenna would have the form of an infinitesimal sphere. The question then is 'which sense of circular polarisation' ... which undoubtedly has nothing at all to do with Coriolis force! The real answer is that it doesn't matter because, as you mentioned (below) such an antenna has an infinitesimally small radiation resistance and cannot be made to radiate.

Mike you forget.
I do not subscribe to the wave theory over the particle aproach.
I cannot see any other way to fit that "radiation is from the
acceleration of a charge". And I can not find any explanation of this
in any books. Only mass is able to have spin and at the same time
transport energy, at least to my mind. Therefore accelaration is the
creation of two forces that are not in the same plain ala a shear
action where the combination of gravity and the Coriolis force are the

weakest forces known in the std model. I would remind you that spin is a result of a force applied where the reaction force is not in the same plane, otherwise referred to as torque ala force times distance. It is quite easy to show that current flow consists of a direct vector and a circular vector
within a boundary and where a direct vector and a circular vector on the outside of the boundary creats a condition of equilibrium. This is just physics per our Universe and now many want to deny physics by intuition alone. I would also remind everybody that engineering, electrical, mechanical or what ever is a subset of the subject of physics where concentration of learning is of a niche of the physics .

Art,

Since there is no "re:" on the subject line I assume you are the initiator
of this post and I have to ask how it's relevant to this newsgroup. You
have also attempted to initiate other off-topic threads. Can't you find a
more appropriate ng or forum for these posts rather than show a disregard
for those coming here to seek info on ham antennas and related issues? At
the very least I would appreciate including the standard "OT:" prefix on
the subject lines of off-topic posts. These kinds of posts illustrate why
moderated newsgroups become necessary. Sincerely, and 73s from N4GGO,

John Wood (Code 5550) e-mail: wood@itd.nrl.navy.mil

I replied to the assertion that my homeland was guilty of embarassment
or shame.

What sort of man is one who does not stand up on behalf of his
homeland where presently their soldiers are standing and dying along
side ours of the U.S.
I am attacked personally daily, but to attack the U.K and the
Commonwealth for declaring war on the German menace, a consequence of
which many gave their lives, is a totally different situation to me.
Hopefully you can understand that and thus allow the matter to drop
without loss of stature
Regards
Art

Thanks for reply, Richard.
Take also into account that, although i don't know much mathematic, i don't have any doubt that is impossible that this kind of antenna can have a great or also medium efficiency.

Considering your 1/4 wave AM broadcast antenna example, is not an accident that nor military nor broadcast installations used in the past a type of antenna like the EH/HZ...
... and military brains have knowledges that we in the "civilian" world can use maybe after 20-30 years.

And, if this really works, one don't waste time writing PDF. He start working in radio with this antenna, and if the antenna is *really* what he claim, he will be in a very short time a rich man.

> 73, Cecil, IEEE, OOTC, http://www.w5dxp.com

Cecil I must respectively disagree. Your arguement is based on the
presence of common mode current. When there is a state of equilibrium
there is no vector that represents common mode. Since the radiator is
a full WL that represents a period it is of closed circuit form. In
such a case any radiator bend is accompanied by a bend that is equal
and opposite per Newtons laws. The moment you introduce common mode

currents you have strayed from the concepts of equilibrium, where all forces are accounted for. Maxwells laws are based on the position that all forces involved are accounted for where the summation of such equals zero.

Cecil you misunderstood what I was saying .
When you use a fractional WL then some of the wire cannot radiate,
thus the impedance is reduced from that of a full WL. Power is still
I sqd R Cos phi. where there is a varience. with the R in this case of
a approx 1/2. Gain is not involved, only energy dissipated.
Regards

... if the first 'nor' should be interpreted as 'neither' then I'd agree.
In the UK, 5/8 wavelength vertical radiators have been popular for AM radio
broadcasting, singly (e.g. used for some BBC services) and in arrays (for
commercial radio, eg. Saffron Green, north London) usually with _very_
extensive earth mats. The Isle of Man International Broadcasting company
made a big deal about ten years ago about their intention to use a CFA for
broadcasting on 279 kHz, initially from the island, and latterly from a
modified oil rig in IOM water (e.g.
http://www2.hard-core-dx.com/archive/1999/msg01127.html). However, this
still isn't on the air so one may speculate.

Gain has nothing to do with energy expended from a radiator. A folded
dipole is of a full WL with an overall dimension of 1/2 WL.

My comments were about a one-wavelength straight
wire dipole in free space. The reflections from
the ends are what result in that large resonant
resistance at the center.

<--Vf
Open <--If
----------------------fp----------------------
Circuit Vr-->
Ir-->

Zfp - feedpoint impedance, Vf - forward voltage,
Vr - reflected voltage, If - forward current,
Ir - reflected current

Zfp = (Vf+Vr)/(If-Ir) = thousands of ohms

However, if we fold the 1WL dipole into a circular
1WL loop it is still a standing-wave antenna but
the phase of the reflections is reversed.

Zfp = (Vf-Vr)/(If+Ir) = ~100 ohms.

Where are those reflections coming from in a
circular 1 WL loop? Why is the phase of the
reflections reversed?

Equilibrium means equilibrium thus there are no reflections. Actions
have an equal and opposite reaction. What are you going to draw upon
for an equalizing vector?

The difference in pattern between a half-wavelength dipole,
and an infinitesimally-short dipole (i.e. one whose length
approaches a point source) is actually quite small. Both are
torus-shaped patterns, with a deep null along the axis of the antenna
(theoretically, the null is infinitely deep directly along the axis).

An infinitesimally-short dipole has a maximum gain of 1.76 dBi.

A half-wavelength dipole has a gain of 2.15 dBi.

There really isn't much to distinguish the two, as far as the pattern
and gain go.

>Unfortunately, the gain drops, efficiency drops, and feed point
>impedance drops, resulting in a rather inferior antenna.

Yeah, the low radiation resistance and high reactance of the short
dipole are its biggest drawbacks.

I'll plug a series of shortened dipoles, possibly with loading coils,
into 4NEC2 and see what happens. You may be right.

As I recall, the big holes in the pattern, that are inline with the
elements gets smaller is diameter as the antenna gets electrically
smaller. The rounded circular donut pattern tends to flatten. I
wanna play with the models to be sure. This still begs the question
of how close to spherical does the pattern need to be in order to call
it isotropic? Dunno.

>I was once told a true isotropic radiator would have to be circularly
>polarised

"Near isotropic circularly polarized antenna"
<http://www.google.com/patents?id=saMgAAAAEBAJ>
CP satellite antenna used on Intelsat V. I've been looking at the
patent for a while trying to figure out how it works.

Yeah, it should be CP because that would correctly fit the definition
of the field being identical along the sphere, in all possible
measurement antenna orientations. Note that the isotropic simulator I
posted is *NOT* circularly polarized. If you plug the deck into 4NEC2
and instead of looking at the total gain in the 3D window, look at the
vertical and horizontal gains individually, you'll see something
really ummm.... interesting.
<http://802.11junk.com/jeffl/antennas/isotropic/isotrop2-vert.jpg>
<http://802.11junk.com/jeffl/antennas/isotropic/isotrop2-horiz.jpg>
Needless to say, that the polarization is not even close to being
uniform over the sphere. (I'll add these to the menu as soon as I can
figure out what the latest JAlbum update broke in my photo
collection).

Drivel: Just got 4NEC2 setup on my new computah (Dell Optiplex 755 E8500 with 4GB). A messy tower and antenna simulation, that took over an hour on my old PIII/1GHz clunker, now takes about 4 minutes. I'm happy (for now).

And for equal, matched power applied to their feedpoints, the total of
the energy "expended" (radiated) by both them is identical.

>or also medium efficiency.

Hi OM,

Efficiency in percent (%) is simple math: 100 * PowerOut/PowerIn

In decibels, I won't show the math, I will give some example:
100% is 0dB
95% is -0.22dB
90% is -0.46dB
80% is -0.97dB
50% is -3dB
10% is -10dB

Look at your S-Meter. If any station added 5% efficiency, going from
95% to 100%, then your S-Meter would shift 0.22dB. The needle of your
S-Meter is probably more than 1dB thick when you look at it. The
needle would then move 1/5th of its thickness when a station adds 5%
efficiency.

I have been in the military - antennas work the same there too. I was
a teacher of RF Systems (LF/MF/HF/VHF/UHF/SHF). There is no magic
knowledge hidden by the government.

>And, if this really works, one don't waste time writing PDF. He start
>working in radio with this antenna, and if the antenna is *really* what he
>claim, he will be in a very short time a rich man.

A very short time needs to be defined. This "antenna" has been around
for a long time and no one has gotten rich (and the buyers have lost
money, time, and signal).

Anyone can write a useless PDF. Anyone can get a useless patent too.
I have observed patent holders who post here that have forgotten their
own patent numbers, their own patent claims, their own URLs, their own
email addresses, and their own theory. Talk about a waste of time,

but it is wasted with the vigor of a seven year old. It would seem that wasting time, money, and signal power was equivalent to earning a PhD in Einsteinomics and advanced Gaussology.

And again today in response to Cecil concerning a full wave loop versus
full wave dipole, equilibrium == no reflections.

I don't think he's sure what equilibrium is except that it's his trump
card in an argument.

Yes if you see it as a particle and not a electromagnetic wave.

Because acceleration is following a parabolic curve beyond which it
has attained the speed of light. I cannot determine the acceleration
as that is a determinate of. L. and C As it happens the speed of
light was determined after radiation which to my mind puts it firmly
into the particle arena

No David, I just went along with your interpretation of same in the
U.S.
For my self I will stick to equilibrium as stated in any dictionary.
So I accept your terms as one to use in the US electrical arena
because you get upset as it may sometimes be equivalent to
equilibrium. But I am not going to fight that battle.
Personally, I am beginning to think hams mix the terms resonant and
equilibrium or is it just the U.S. One day some body is going to say
gottcha that is inevitable with so many hits
but that is not one of them.

there is no reference for 'equilibrium' to be applied to electromagnetic
radiation. is just doesn't exist. so you have now given up all your
credibility by not sticking with what you admitted was an equivalent of your
term 'equilibium' in 'isotropic'.

The applicable law by Newton states ut +ft sq/2. Without a value for
time acceleration cannot be stated. The circuit is one of a tank
circuit so one has to state the frequency as well.Acceleration is the
ratio between root W.L.as well as frequency so again acceleration
cannot be stated without all the facts. Time is measured by the time
two fields are interacting after which the particle maintaines a
straight line projection. The interaction is parabolic in nature in
all cases. The fields are electrical by the way tho all mechanical
movements can be expressed in electrical terms

For clarity I should have included the fact that the total of the energy "expended" (radiated) when equal and matched powers are applied to any and all elemental radiators, of whatever form, essentially is identical.

What is NOT identical across these various radiator forms is the field intensity in specific directions in the radiation volume.

THAT depends on the design of the radiating structure(s), and the installation+propagation environment.

This is the reason for the 1.6 dB advantage in the intrinsic, free-space, peak gain of the full-wave dipole over the 1/2-wave dipole in the NEC analysis I posted earlier today. Both of these configurations radiate the same total energy (somewhere).

But along their axes of maximum radiation, the full-wave antenna produces the greater field intensity of the two, for a given applied (and matched) power source.

Straight and clear. Well, maybe my knowledge of physics and mathematic can
go a bit far, including understand e.g. ground losses, path loss in free
space, takeoff angle, feed point impedance and other silly things regarding
antenna world :) but sorry, Maxwell equations are a bit harder for me :)

> I have been in the military - antennas work the same there too. I was
> a teacher of RF Systems (LF/MF/HF/VHF/UHF/SHF). There is no magic
> knowledge hidden by the government.

Well, i'm ever a optimistic mind... i just think that maybe tomorrow i can
use something better antenna thanks to MIL research ... like a trick to
build a 160m yagi in the same space of a 40 m yagi :) of course, just
joking... OTH radar DUGA-3 in Prypiat, ex USSR now Ukraine, is a good
example for me, MIL also need big antenna system.

Well, let say that *today* is more obvious and easy that this total waste
happen. Globalization and the internet make very easy for timewasters to get
a large public for the things they are saying/writing/claiming. And the

same, in a reverse way, happens to the skilled people, that have occasions to read tons of wrong assertions on the internet. Many years ago the worst case is to listen to timewasters on a local repeater or on a 40/75/80 meters net.
When i don't understand something, the first thing i do is ask, ask and ever ask.

Unfortunately, today is easy in the same manner both turning on a computer and turning on a radio to communicate with other people.
Unless you don't have a wireless connection, the computer have as a bonus that don't need any kind of antenna.

Thanks for your time,

-.-. --.-, Cristiano, Italy.

Nope. You're still an ass. I believe the term the current geek
generation uses is "asshat".

And your mistaking criticism for being pushed around. You are the one
calling pretty much everyone, including those that have managed to make
a living designing and installing antenna systems, idiots. Expect to
get hard pushback when you do that, especially since you haven't managed
to produce one solid provable fact or testable hypothesis for the group.

Bafflegab is just bafflegab, Art, and that's all anyone's seen to date.

> Remember my WL is a closed circuit

Believe it or not, there are reflections at the
feedpoint caused by the Z0 physical impedance
discontinuity. You would be correct only if your
"closed circuit" was a traveling wave antenna.
But if it was a traveling wave antenna, its
feedpoint impedance would be in the hundreds
of ohms which, I assume, it is not. The fact that
your antenna doesn't have a feedpoint impedance
equal to the Z0 of the antenna wire proves that
reflections are present.

W8JI made essentially the same mistake in his loading
coil delay measurements so don't feel bad about it.

> I will wait for that day.

No need to wait. It's easy to make the measurements
for yourself. I have already done it to prove that
standing wave current, with its unchanging phase
relative to the feedpoint current, cannot be used
to measure the phase delay through a loading coil.

If a current probe is used to measure a traveling
wave, the amplitude will be constant. If the amplitude
changes from point to point, it contains a standing wave.

Of course torque is a force. Ask any auto mechanic.

I am more familier with the Corriolis force as
it applies to weather. IE: the spin of huricanes,
the rotation of weather around low pressure systems.

I am unaware of a single regular contributor to this newsgroup that would refuse to give an example, however simple or complex, of an antenna that PROVES that what they are claiming is true.

Usually they are correct, sometimes it is arguable, seldom is anyone wrong. But I've never seen anyone not step up.

Until Art Unwin.

Who refuses to prove anything.

Give us something to test or shut the hell up. You are boring.

Nonsense. Personal attacks are the surest way to victory. Study any
successful politician and you will have no need for me to explain further.

Examine the dreck that fills up your mailbox on Friday and Saturday before
any election day. It's not pro-candidate; it's not pro-anything; it's all
god-damn-my-opponent -- and they're called "hit pieces" for good reason.

Saint Edward of Massachusetts, aka Teddy Kennedy, was civil when it suited
him but he engaged in the vilest of character assassination* the rest of the
time. It didn't matter as long as he could cast his target upon the trash
heap.

*Bork was a man's name. Senator Kennedy made it a verb.

Sal

Hi Cristiano,

The only people that rely on things like Maxwell's equations, or
Gauss' Law are those who don't know the math.

You don't need that math to discuss 99% of the art of design. That
math might be mentioned, but whoever is trying to use it as their sole
point of discussion is someone who is lost.

Military designs and commercial designs did lead the way for practical
antennas .... 70 years ago. If you want to build an 160M version of a
RADAR antenna you might get more argument from your neighbors than you
will find here. That huge antenna will show every characteristic at
160M as it does at SHF, but you better be pointed in the right
direction.

Tom You are losing it and getting worse. Why don't you block my posts?
That way you will not lose any sleep. I just smile when you post but
in return
you get so angry you don't make much sense it terms of a response
Right from the get go all denied that adding a time varying field to
Gaussian static theorem provides mathematics of radiation as taught by
Maxwell. Until this group recognises this it is pointless to proceed.
You will just have to live with that until all can come to terms with
that statement.You will not read it in any book so you have to go back
to first principles for yourself. If your learning in life is based on
rote or memorizing books then you are out of luck. If you can't come
to terms on that then it is you who is the fraud
Failing that you will just have to rely on intuition instead of
mathematical facts

> the rotation of weather around low pressure systems.

Excellent Gordon and the particles are connected to the weather
When particles arrive from outer space they reside on diamagnetic
substances and water is one. So when there is an updraft clinging to
the water droplets are these particles which gather a charge with
elevation until the moisture cools and there is no room for them to
stay. These particles are now electrically static charged where when
broken loose move to ground or the other side of the capacitor. Thus
we all see a lightning strike which is an electical static field. This
same charge circulates the earth one way above the equator and and ony
way below the equator such that the shearing action occurs which is
the circular motions that we see everywhere in life. These same
charges cling to space suits in outer space because the human body is
mainly water. NASA has had some luck by discharging the suits to a
ground as one would do with a capacitor so the abrasive particles do
not enter a ship. Without charge the particles are basically inert
like a unbound electron'
For the life of me I do not understand this stance that a shearing
action does not create spin or torque. A real crazy group of experts.
As far as pressure deviations in weather this is exacty the force we
see in eddy currents of electricity as well as mechanical things such
as tornadoes. All four forces involved in the Big Bang are the only
forces involved in the Universe because of the Newtonian laws so use
of the boundary laws are indispensible
with respect to all that happens, chemical, electrical, mechanical or
what every where energy units such as volts etc are inter convertible
metrics. And the electrostatic field is a isolated phenomina that has
zero connections to laws of this Universe
Thanks for your involvement on this issue.
Regards
Art

Sadly true, But that does not follow the edicts that demands care of
our fellow man which also spills over to the health care of the poor.
Collective mental and physical harm given to provide superiority for
the haves over the have nots is just a grab for personal advantage
during a life against those who are unable to resist. If you believe
the equation that all comes to an end with death then this is logical,
But what if life transfers to another different life chosen by a true
superior? Do you think you can repeat such tactics at that time and be
succesfull ?

I said "avoided", not eliminated entirely. There are places where
character assasinations are both useful and successful. As you
indicate, politics is one of these. There's also advertising,
competative bidding, and stealing someones girlfriend. All is fair in
love, war, politics, advertising, but not antenna design.

>Examine the dreck that fills up your mailbox on Friday and Saturday before
>any election day. It's not pro-candidate; it's not pro-anything; it's all
>god-damn-my-opponent -- and they're called "hit pieces" for good reason.

You're being too generous. It has been demonstrated that candidates
can win an election without ever mentioning any issues. Even the dead
have won elections. However, none of these politicians have ever
designed an antenna, so I suspect that this phenomenon would not be
particularly applicable.

>Saint Edward of Massachusetts, aka Teddy Kennedy, was civil when it suited
>him but he engaged in the vilest of character assassination* the rest of the
>time. It didn't matter as long as he could cast his target upon the trash
>heap.

Hint: You don't make it to the top in politics (and business) without
stepping over a few bodies. Much as I would like this to cease, I've
seen no indications that this will ever change. However, with debates
over antenna design, we still have the option to act in a reasonably
civil manner. In general, most of those posting questions and answers
in this group are quite civil and usually (not always) concentrate on
the merits of the design or problem, rather than attacking the
invidividual. Simply demonstrating that there is a class of
politicians that violate good taste, proper manners, and logical
arguementation, does not automatically give everyone in this newsgroup
a license to act in a similar manner.

>*Bork was a man's name. Senator Kennedy made it a verb.

Name calling also is common. Same logic. Just because politicians do
it, doesn't license everyone to follow in the same manner.

A dipole is always the two monopoles and never a point source. Only monopole
is a point source.

> S*

Nonsense. Only a point can be a point source.

The principle of the infinitesimal electric doublet is the hypothetical result of making the lengths of the elements of a balanced dipole vanishingly small. This is useful to quantify the characteristics of the limiting case but, because of its inherent axial symmetry, it still has the form of a dipole and the same kind of radiation pattern with linear polarisation and no radiation in the directions aligned with the ends of the dipole (for the reason I gave earlier in this thread).

Monopole antennas are developed from dipoles by substituting one of the elements, often using a 'reflection' of the remaining element in a ground plane. Their characteristics are different from those of the parent dipole because of this substitution but they still have the same kind of axially-symmetric radiation pattern, with linear polarisation and no radiation in the direction of the end of the monopole.

A point source is a hypothetical 'device' that radiates equally in all directions. Obviously this could not be realised using a monopole because that would provide the wrong radiation pattern.

A polarisation can be assigned to a point source, for the sake of comparison with real antennas (which is how the point source is used), just as a point source can be considered as transmitting or receiving a signal - but that doesn't mean a physical antenna can be made that has the same characteristics, that can be made to transmit or receive.

Chris

there is no such thing as a monopole antenna. unless you have discovered
the magnetic monopole somewhere?

> the rotation of weather around low pressure systems.

And that is what the Coriolis force is. It's a mechanical effect, and not an electrical one.

Art is trying to convince us that EM energy is also a mechanical force, consisting of particles that fly off the end of our antennas like little turds. The ramifications of that means that everything we thought we know about RF - and in fact all physics is completely wrong.

A test can be performed easily.

If RF energy has mass

It then follows that a transmitting antenna will lose mass.
Likewise, a receiving antenna will gain mass.

The confirming experiment can be made by using a two small antennas in
an isolated environment. One is transmitting, and one receiving. If RF
energy is a particle - therefore mechanical force, the receiving antenna
must accumulate mass, and the transmitting antenna must lose it.

We do have the needed resolution of measurement to make that test.

That is the presently accepted formula in science where atoms are
removed from the matrics of the radiator.

For me, all diamagnetic materials are completely covered with particles that entered the solar stream from the Sun. As soon as they are projected away from a radiator another takes its place, thus no changes in mass.
When placing such an arrangement in boundary form on the outside is the vectors of gravity and the Coriolis force. On the inside of the arbitrary boundary
are the vectors of a moving charge together with a spin action of a eddy current together with a particle at rest where all transforms in to a projection with spin of the static particle.
This breaks the arbitrary boundary and where the arrival of another static particle restores equilibrium.
This mechanism is the same as that from the sun when equilibrium is broken by the escape of such particles because of the exchange of potential energy to kinetic energy within its boundary.

See David,
I do take notice and remember your statements of the past
Check the archives for accuracy.
I too had a good laugh when you came up with that
as your position with respect to physics. What surprised me was that
you were seen as a role model and every one else followed in step. To
this day the group accepts your
position on physics that you cannot add a time varying field to
Gauss's law of Statics.
Two different things, you said, where one has no association with the
other so the premise that Gaussian law then becomes the same as
Maxwells laws is a faulty application and should not be done. Oh my!
What a short memory you have. And remember when you dissed that Doctor
from MIT who agreed with my premise and then everybody assasinated
him as a fool. As for me I am not going anywhere I holding to my
premise
Have a great holiday.

> If RF energy has mass ...

The mass of each photon is:

m = e/c2 = h/c*lambda

where h is Planck's constant, c is the speed of light,
and lambda is the wavelength.

The reason that your experiment won't work is that
equal amounts of energy are being supplied to and
radiated (or conducted) from a transmitting antenna.

Where exactly does a photon come from and what does it consist of?
Mass with potential energy or what? This word is bandied around so
much
but its existence has not been verified as yet by it's capture!
This approach has handicapped the advance in physics and radio for
over a century now.
Should we not explore a different avenue to see if answers lay
elsewhere.? Why do we resist change to so called accepted analogies
and theories? Why is this group so confident
that particles are not involved because it is an electrical thing? If
one accepts kinetic and potential energy why do they fight the
presence of mass?
Regards
Art

You have made a small mistake. Antennas are feed with the oscillating
voltage. So the little truds fly off and come back. It is normal
longitudinal wave.
The key problem is what radiate: the end of an antenna or something else.
What do you think?

No, you've made a mistake ... again. EM waves are transverse waves in air (i.e. around a normal antenna) not longitudinal waves (see http://en.wikipedia.org/wiki/Longitudinal_wave). Sound waves are longitudinal because air pressure is a scalar, whereas electric and magnetic fields are vectors - they have polarisation.

Also, antennas that radiate are fed with alternating current. The terminal voltage is almost immaterial in comparison with the current - that's what causes the radiation.

If you want to discover what radiates I suggest you read one of the normal text books on the subject, like Kraus 'Antennas', and stop making up your own versions!

Chris

So now we have left science, and as far as I can tell, have entered religion.

I was totally destructed and reconstructed 100,000,000 times this morning.

Prove I wasn't. Art's particles did it. Every atom in my body has been shed and replaced 10 times that while I typed this note.

Seriously, you guys want to de-construct everything we know and replace it with religion? Ooookay, I was taught a long time ago to avoid religious arguments, so have fun, kids.

Yes. Monopole made of wire is not a point source. For this reason inventors
mounted something lake a ball on the end.
>

Each todays dipole consist of the two monopoles in opposite phase.
There are the two seperate sources. They produce the two spherical waves.
You say they are polarised - I that they are coupled.
>

Equipment is polarized - not waves. Point sorce cannot be polarised. The two monopoles are always polarized. Long wire without big tip is pseudo-polarized.

Photons are quantized elementary particles in the standard
model. Every time you see something, like this posting of mine,
you are capturing the photons incident upon your retina.

Double slit experiments with photons have been performed
with a single photon which apparently can go through both
slits at the same time and interfere with itself on the
other side. Those photon detectors indeed can capture
individual photons.

Photons are quite often generated and detected within
particle accelerators.

The math has not to do here.
Here is the full acoustic analogy. The two loudspeakers work like the two
monopoles.

To discower what radiates will be better to do experiments with tipping of monopole antenas.

It is usually impossible to prove a negative. You might
have only been destructed and reconstructed 99,999,999
times this morning. That's why the onus of proof is upon
the one who makes the positive assertion.

What would you say if the police knock on your door and
demand that you prove that you never ran a red light?

> Is he right?

different context... "Monopole" antennas as he is describing are a specific type of antennas that are otherwise described as 'verticals', 'ground plane', or several other terms.. all of which actually are dipoles in the context that they have 2 poles, not that they look like a 'half wave dipole' which is a special case of a dipole. In his context it refers to a vertical with some real size greater than zero. in your context the 'monopole is a point source' means you think that a point source is a monopole which is impossible since a monopole(meaning single pole) can't radiate. His description is a bit simplified, but otherwise reasonable for a "Monopole" antenna, but you must always remember there are 2 poles even in a "Monopole" antenna... just one of them is the ground screen or radials.

Where on earth did you get that thought from.? Or is your intent to
mess up the minds of everybody? This line "Art is trying to convince
us that EM energy is also a mechanical force consisting of particles"
Where did you see that comment? As for things flying of the ends of
an antenna where did that idea come from?
Everything in this world can be converted to electrical units! What
you want to label them
at any particular time is fine by me. But untruths are something else.
Is this what your presence in this discussion you intend to propagate?

Years of discussion on this same subject has been a matter of lies,
misinterpretations and a determination to obstruct change.
All of these discussion rest on a statement made years ago which has
since gone on to many tangential discussions based on untruths.
The original statement, made by me was:

"If you add a time varying field to the laws of Statics by Gauss the
mathematic results are in full conformance with Maxwells laws"

It is this statement that the group is up in arms about ! Yet they
want me to explain the antenna that is a direct result of the above
statement. A statement they refuse to accept where their response has
been character
assasination which has failed because I am still here.
It is a simple statement which is exact and true which all are
fighting to prevent this from being accepted. Why? Because of a
reluctance to embrace change because of age.
Thus for this representative group they are content that all is known
as printed in the books and trying to convince the World there is no
need for further discussion. So I ask, what is the real reason hams
take this position if in fact they are represented by this newsgroup
of self perceived experts?

EM waves in an unbounded medium, far enough from a source to be in the far field, have a longitudinal component only if the medium has loss. In air, the fields are for all practical purposes purely transverse as christofire says. Hence the descriptive name for the field orientation as TEM for Transverse Electro-Magnetic. This is also true of some bounded media such as coaxial cables, where again the fields are transverse except for a usually small longitudinal component caused by loss. But in other bounded media such as waveguides, one field or the other (electric field in TM mode and magnetic in TE mode) can be longitudinal. You'll also see a longitudinal component when a wave gets close to lossy ground, although it's typically not large compared to the total field.

Roy Lewallen, W7EL

My problem is with how photons fit in with radiation?
It is a nice name but how does it get launched and where did it come
from?
Personaly I can't distinguish it from a particle at rest on a radiator
or how it can possibly get attached to it which apparently you
believe. I just want to see how this proton fits in with what we know.
Waves or particles.

Chris, what I believe he is referring to is that computer programs
support a tipped vertical over one at right angles to earth. Computer
programs are supposed to be based on Maxwell's formula. Is this an
error and how do we fix it. If it is not an error then it supports the
presence of the Coriolis force in collusion with gravity. and not
gravity alone.
More to the point, it is common knoweledge that there is no full
understanding of radiation
available anywhere. Thus he is asking probing questions to fill in the
gaps.
Personaly I am not willing yet to say antenna programs are at fault
until more explanations come about. Can you explain what he is
commenting upon.?

The crap is with us to stay. I didn't invent it. Recognizing it shouldn't
be an offense.

My response was to what I perceived to be an overly-idealistic viewpoint
about it. Politicians aren't statesmen -- they're simply opportunists.

Who refuses to prove enything."

I don`t think Art needs to prove that a 1/2-wavelength of wire behaves as a reaonant 1/4- wavelength under proper conditions. It has been so reported many times by many reliable reporters and should have become common knowledge long ago.

I`ll quote only one source as I have no appetite for digging through many dusty volumes right know. That source I consider very reliable is "The 20th Edition of the "ARRL Antenna Book". On page 6-28 it says: " The quarter-wavelengrh helically wound vertical can be used in the same manner as a full-size vertical. That is, it can be worked against a wire radial system (four or more radials) or it can be ground-mounted with radials buried or lying on the ground.

On page 6-29 it says: " "Experience has indicated that a secrion of wire approximately one half wavelength long, wound on an insulating form with linear pitch (equal spacing between turns) will come close to yielding a resonant quarter wavelength. Therefore, an antenna for use on 160 meters would require approximately 230 feet of wire, spirally wound on the support.

Art may have discovered the above alone but he was very unlikely to have been the first discoverer.

Best regards, Richard Harrison, KB5WZI

where do you put in the Coriolis effect or gravity direction in your
computer modeling program? i haven't seen one yet that let you put those
in, or even the latittude that could be used to derive the effect from.
without those you are just tipsy.

my statement still stands. Gauss's law IS one of Maxwell's four equations, and it doesn't need you adding a (t) to it to make it work any better than it has for the last hundred years or so. The basis is that Gauss's law is independent of time, so it is true AT ANY TIME, it doesn't need a time parameter to make it work. if you really want to you can add a (t) on both sides of the equation, but it won't change anything, it just clutters up the notation.

Richard

I don't have any issues with spiral wound loaded antennas. I have several hamsticks which fall in that category.

Perhaps you've missed the parts where he claims performance including gain and especially directionality from a 160m antenna that is perhaps the size of a shoebox. And has windings in one sense and then in the other. That's the stuff he won't and can't prove works as claimed. And I just remembered the part where he's going to put a DSS style dish behind it to make it even more directive.

And then there's the imaginary physics that he claims makes all antennas work.

Sorry, I stand on my statements.

Chris, what I believe he is referring to is that computer programs
support a tipped vertical over one at right angles to earth. Computer
programs are supposed to be based on Maxwell's formula. Is this an
error and how do we fix it. If it is not an error then it supports the
presence of the Coriolis force in collusion with gravity. and not
gravity alone.

* I don't doubt that it is possible to obtain results from a computer
program that appear to contradict conventional theory. Interpretation of
what comes out is always the responsibility of the operator so, whilst
anyone can enter parameter values and hit 'go', not everyone will interpret
the results correctly. In this respect it must help greatly to have a clear
understanding of the basic principles of how antennas radiate and how the
modelling programs operate; in most cases how the moment method works. My
recommendation, as before, is to read an edition of 'Antennas' by Kraus (or
an equivalent), cover to cover, before trying to make sense of the output of
any antenna modelling program. Of course, I realise that some who 'publish'
here feel this would be beneath them, or too hard ... but, really, it is
neither.

My own take on the effect of tilting a vertical antenna is that if its
length is an appreciable fraction of a wavelength then tilting it will
distort its radiation pattern and will upset the uniformity of its
polarisation, which will impose a further effective radiation pattern. If
this results in a bit of gain in one particular direction with respect to a

particular polarisation then fine, and this may be of some use in amateur radio service although it isn't how vertical monopoles are most often used (i.e. their omni-directional pattern is their strength and there are many other, better ways, to obtain directional patterns).

However, the theory on which all the well-known modelling programs is based is the simple stuff described by Kraus, et al, and probably in most cases follows from the original work that led to NEC (http://www.nec2.org/other/nec2prt1.pdf). It takes _no_ account of the Coriolis force or gravity (outside of its impact on the speed of light). If such a program produces output that the operator interprets as depending on the Coriolis force then, logically, this must be a mistake on the part of the operator - wouldn't you agree? However, if you believe the theory on which the program is based is in error then maybe you shouldn't use it.

More to the point, it is common knoweledge that there is no full understanding of radiation available anywhere. Thus he is asking probing questions to fill in the
gaps.

* There is sufficient understanding of radiation and antennas out there, as widely documented, to have enabled practical radio, radar, and suchlike for more than a century. I understand that part of the point of amateur radio is to encourage experimentation, but I don't understand why experimenters should wish to shun the accepted, conventional theory and try to come up with their own, perhaps paraphysical, versions - especially when those people don't exhibit much understanding of the basics. Maybe they treat the subject a bit like art (no pun intended) instead of the science that it should be.

Personaly I am not willing yet to say antenna programs are at fault until more explanations come about. Can you explain what he is commenting upon.?

* It's possible he is being deliberately provocative.

Chris

It is conceivable that the Coriolis effect may act upon EM radiation.
But given the speed of propagation of the radiowaves the effect would
truly be miniscule. I Art thinks the rotation of the earth has any
significant effect on EM propagation he should show some reference. Im
not going to hold my breath until that happens.

Jimmie

oh yeah, i forgot the laser beam pattern... was it also circularly
polarized, or was that some later rant?

the key with the coriolis effect is that the earth turns under something
that is moving north or south at different rates. it doesn't affect what is
moving, that still follows normal physics... so basically something launched
from the equator going north will have a higher velocity to the east than an
observer north of it so it will appear to bend to the east. it really
didn't, its just that the observer didn't move fast enough to keep up with
it. that is why it is an 'effect' and not a 'force'. the object travels in
a normal ballistic path as if the earth wasn't there once it leaves the
launching point... so if you shine your laser north from the equator it will
'appear' to bend east, but if it did actually follow the earth's curvature
it would only very slightly miss the north pole.

O.K. No problem
Now let us see what others have to say. After all it is a academic
question
related to electrical engineering and there are many engineers around
beyond the self perceived versions.

I have always followed the particle approach over the EM route. The reason I have followed this path is that Gauss's law dictates it and computer programs support it. There has been no move to doubt programs so I assume they are according to Maxwell and the errors are else where. So let's go back and leave these assertions that have been erroniously pointed at me and look at the Gaussian/ Maxwell observation which I have pursued. I have posted the original statement and look for those who have expertise in the area to post their views and why. So Jimmie you have been prolific with your thoughts and insults, allow us to view the mechanics of what ever decision you make whether it is a repeat of David or one that shows your own method of thinking.
Thanks in advance
Art
Dave has posted his reasons why he feels my assertion is false

see, he still doesn't understand that Gauss's law is one of the 4 basic
Maxwell equations, always has been and always will be... without his extra
time parameter or anything else. he thinks he has discovered something new
by adding Gauss's law with time into the equations.

Oh come on .you are riding on each others misinterpretations.
Pointless to follow this course. Watch the other thread on Gauss/
Maxwell.
I am sure there is somebody with some smarts that can state
specifically why it is correct or incorrect and just not shoot from
the hip with personal intuition. If the statement is in error then
every thing else falls apart. You don't need a character wipe out now.
The question of mine that is placed is clear and concise and I have
declared ownership of that statement.

Chris I assume that you have a computer with an optimizer so you are
aware that it will follow the intent of Maxwells laws. And if you
allow it to do this the input should not be designed for planar forms
but allow the optimizer to do its thing. When it finishes it will
provide a response of 100 percent accountabilityYou know this because
maxwells laws account for all forces such that it then provides a
tipped radiator But if you feel it is operator error then what did
your program supply with that input or is it you do not own or use an
optimizer which seems to be prevalent on this newsgroup. Soooooooo

address the statement made by me and provide an academic response since all posted on this subject comes back to that simple statement I made. All the other postings are distortions that have run amoke such that nobody knows the subject of debate and it has become a joke. Your input to the statement I am sure from your comments will be academic in form and greatly appreciated. I am winding this thread down now as statement made are being attributed to me which is false and errors are piling up on errors

Such a helical may come close to resonance, but unless the overall length of the helical structure approaches 1/4WL, its radiation resistance (Rr) will not be as great as if a naturally resonant, straight, ~quarter-wavelength conductor is used.

Lower Rr for "monopole" antennas will reduce the radiation efficiency of these systems -- if they are not using a zero-loss r-f ground connection.

Bachelor O'Science, Electrical and Electronic Engineering.
Cal Poly, Pomona (1971).

1. There is no such thing as Gauss's Law of Statatics, Statics,
Statistics, or Silliness. Please find and use a spelling chequer.

2. Maxwell's first two equations are Gauss's Law for electric fields
and Gauss's Law for magnetic fields.
<http://en.wikipedia.org/wiki/Maxwell%27s_equations#General_formulation>

3. Gauss's Law roughly states that the total electric flux through a
closed surface is proportional to the total electric charge enclosed
within that surface. Note that neither the flux or the charge are
moving.

4. Unless you want to add quantum or relativistic variables, a static
field or charge does not need to have a time variable. If you insist
on adding it to Gauss's Law, it will appear identically on both sides
of the equation and cancel. That's because you cannot have time
moving at different rates on both sides of an equality.

Youtube lecture on Gauss's Law (from India):
<http://www.youtube.com/watch?v=whv_d-fBCg0>
It's 1 hour long. The speaker is very good at deriving Gauss's Law
from Coulomb's. I hate to admit how much I had forgotten. So far,
I've watched about half the lecture. I'll watch the rest later
tonite.

Somewhere somehow mass must be transferred under your system. Particles leave and particles come.

It isn't just that energy is supplied to the antenna from the radio, which gets these particles from the electricity provided to it, which gets it's voltage from something.

Somewhere along the line something has to lose mass, unless magic or supernatural forces are involved. How does the mass from the last thing in the chain go back to the first thing in the chain?

Given that Coriolis is an effect, what would be the cause of the
supposed spin?

Do the spun up particles that accelerate at the speed of light and are
replaced by other particles follow a curved trajectory through the
universe? Do the particles that replace them have identical spin?

I already mentioned that in which case the rifling on a gun would need to be in a different direction depending on the hemisphere, and no rifling would be used at the equator. No answer.

Bullets do not use spin to utilize the Coriolis effect, they use spin as gyroscopic stabilization.

Quick! Tell your local broadcaster.

We don`t need theory to show that antennas for transmitters and receivers work best together when they are exactly parallel in space unless something in the transmission path is redirecting the polarization of the signal. In aligning microwave antennas humdreds of times, I`ll swear this is true every time, regarfless of Corriolis, no matter which side of the equator I was on. Try it. You`ll be convinced too.

No, that wasn't me.

At the time, I was WB6EEP. I later morphed into WB6SSY and recently upgraded to AE6KS. I was playing with Low Band, VHF, and UHF commercial FM radios in college. I built a 6 meter FM repeater with phone patch even before I went to Cal Poly so that I could make long distance calls for cheap from the dorms.
<http://802.11junk.com/jeffl/pics/Old%20Repeaters/slides/wb6eep-01.html>
Yep... tubes. I was also involved in building several local ham repeaters and worked part time at a local two-way shop.

A radio like the AN/PRT-4a would have been useful:
<http://www.prc68.com/I/PRT4R9.shtml>
<http://www.kpjung.de/e_prr.htm>
However, I don't recall ever seeing one around the skool, or in use by any of the other hams. Mostly we preferred GE, Motorola, and RCA commerical FM radios (in that order), which were available in abundance as a result of the original FCC narrow banding ordeal process.

Also, just before I was graduated(1), I was in a state of panic and in danger of getting drafted. I had to quit all outside activities, including part time employment and ham radio, and study sufficiently hard in order to insure that I graduate. Failure would have meant that I would probably get to use one of those squad radios, in Viet Nam.

(1) The debate among the instructors was whether to fail my senior project, thus requiring me to take another year of classes, or to get rid of me by handing me my diploma with instructions go as far away as possible. Fortunately, the latter group won.

Ummmm.... Faraday Rotation?
<http://en.wikipedia.org/wiki/Faraday_effect>
It's not too horrible at microwave frequencies, but becomes noticeable as the frequency decreases. I've done some crude polarization studies at VHF and UHF frequencies with a rotating dipole, and found some rotation on line of sight paths. However, we were looking for a polarization distribution and didn't really spend any time getting accurate numbers for a line of sight path.

Also many broadcasters use elliptical polarization (a mix of horizontal and vertical). However, that's not to eliminate any Faraday Rotation effects. It's to deal with the effects of reflections and refraction, which create nearly random polarization at the receiving end. Also, because stationary broadcast antennas are horizontally polarized, while vehicle mounted broadcast antennas are usually vertical.

I was once asked why the British drive on the left side of the road. My instant answer was Coriolis Effect. I claimed that due to the earth's rotation, it's easier to make left turns on the left side of the Atlantic Ocean and easier to make right turns on the right side of the Atlantic. It took an excessively long time for even the sharpest student to catch the joke/hoax. Sigh.

Drivel: At 2.4GHz, most wi-fi wireless routers use vertically polarized rubber ducky antennas. Yet, most laptops have their antennas in the top of the LCD frame which are horizontally polarized.

Same with PCB antennas found on most PCMCIA cards.

Anyway, nobody cares much about antenna polarization:

That is my setup but I put large 4 inch plastic tubing in the trench
so that the innards could be easily removed, inspected and added to
without having to re dig the trench each time.
I left a heavy wire in place to make it easy to make changes over the
years. Because of the length underground and then the tower I used 7/8
heliax. I also placed a pipe into the tower concrete so I could place
the coax inside the tower if I wanted without the possibility of the
mower hitting it.

Nope.
The Corilis Effect that I am familier with has nothing to do
with particles from outer space. It's just a mechanical
force related to the spin of the earth.

Well, if it were me and more than a few feet, I'd rent a trencher for
installing sprinklers systems and put it all in a PVC pipe with
downward facing elbows at each end stuffed with foam to keep bugs
and water out.

Mine has been out there for about 6 years and no water or bugs yet...

>of him.

Not me. Somewhat after Cal Poly Pomona, I went to Israel for a short
while. When I returned, it was Smog Angeles -> Capitola -> Santa
Clara -> East San Jose -> and finally to Ben Lomond. The family
accountant had an office in Thousand Oaks, but I never lived there. I
don't recall any other Jeff at my college that was also a ham.
Sorry(tm).

>am a non technical person.

Ummm... you don't use a balun to match a long wire. Balun means
"balanced to unbalanced". A long wire is unbalanced. So is the 50
ohm output from your radio. If the antenna were a dipole, which is a
balanced antenna, you might need a balaun, but not a long wire.

Search Google for an "antenna tuner" claiming to match any antenna to
50 ohms. There are plenty of construction articles online, but you
need to know if you're building a QRP tuner, or a kilowatt monster.
Some indexes:
<http://www.arrl.org/tis/info/tuner.html>
<http://www.dxzone.com/catalog/Antennas/Tuners/>

If you wanna buy something ready to go, I like LDR automatic tuners
and MFJ for cheap tuners. Be sure to build or buy something that will
handle the frequency range and power output of your unspecified
xmitter.

I just hate to admit that Art is right (this time only). Conduit is
the way to go. Don't direct bury the cables. Bury conduit and pull
the cables through.

Incidentally, a local state radio building went cheap and used direct
burial cables. 3 months later, the whole mess failed. I popped the
pull box cover and discovered that the gophers had chewed through the
coax and control cables.

I don't know what manner of ground you're working with, but you might
consider horizontal drilling. See:
<http://www.borit.com>
About $250 or available from your local rental yard. Most plumbers
and electricians have one or something like it for laying conduit
under driveways and sidewalks. The standard back reamer is about 5"
diameter, which is about right for 4" I.D. schedule 40.

Otherwise, you get to do some trenching. Sweat or Ditch Witch from
the rental yard. You decide. You'll need to go considerably deeper
than 6 inches. Check your local electrical code, but as I vaguely
recall, it's at least 2.5 ft. Putting 1.8" of dirt on top of a 4.2"
diameter pipe just isn't going to work. The first time someone drive
a vehicle over the conduit, it's going to crack. Dig deeper.

Actually, I'm not sure that 4" diameter will work. Measure or calculate the required diameter. Just use a circle template and draw the bundle on a piece of paper. Leave PLENTY of extra room. Be prepared to leave extra space to pull the RF connectors through (one at a time) or you'll be cutting off some expensive Heliax connectors. Don't forget to leave a polypropylene pull line in the conduit for repairs and additions. You'll need 100 meters of line as you need to pull a new line through with every wire pull. 30 meters is a long way for a conduit pull. You may need to get some slimy cable lube to make it easier. You can try to pull the whole bundle through at once, but I don't think you'll make it, especially with 90 degree elbows at each end.

Put some effort into making sure that the conduit is waterproof. This is best done by proper gluing and testing with an air compressor and bubble soap mix. I'm partial to sealing the ends and pressurizing the conduit, but that's overkill for the typical ham installation.

You'll need a 90 degree elbow at each end. Use the largest radius you can get away with. Heliax does not like to be snaked around sharp corners. You'll also need some kind of protective cover or rams-head at the conduit ends. You don't want the open end of the conduit pointing up and acting as a funnel.

You should also get some useful pointers from the Tower Talk mailing list:
<http://www.contesting.com/FAQ/towertalk>

In case you haven't noticed, this is a bit more than a weekend project. It's also not cheap. Good luck.

Not an effect, not a cause, not a force, not an energy, not a power,
not even a spin: Coriolis is a twisted perception.

If Art were to stumble in the woods and saw you flip simply because
his frame of reference swished, would you feel it? Were you pushed in
- or knocked up? Did you trip on the wall - or did the floor fall on
you? Would you fall clockwise, or counter-clockwise depending on
which hemisphere you are in?

Most of the last few days posts read like a bad LSD trip for a patent
examiner.

You must measure the mass after the halve of the cycle.

```

Maxwell ASSUMED that the aether is a solid body and ASSUMED that there are
the transversal waves. Next he do the math to it. To prove it he asks
Michelson to measure the movements of the Earth in this solid body. In 1878
(about) Michelson did not detect 30km/s. In 1925 he detect 0.4 km/s. It
means that the eather is not a solid body. The EM theory is only math (a
piece to teach).

The first step should be dicovering which part of the oryginal Hertz dipole
radiate:
http://people.seas.harvard.edu/~jones/cscie129/nu_lectures/lecture6/hertz/Hertz_exp.html

The big sparks (current) or the plates (balls).
Note that todays dipoles are quite different. Now no current between the
tips.

Chris I assume that you have a computer with an optimizer so you are aware that it will follow the intent of Maxwells laws. And if you allow it to do this the input should not be designed for planar forms but allow the optimizer to do its thing. When it finishes it will provide a response of 100 percent accountabilityYou know this because maxwells laws account for all forces such that it then provides a tipped radiator But if you feel it is operator error then what did your program supply with that input or is it you do not own or use an optimizer which seems to be prevalent on this newsgroup. Soooooo address the statement made by me and provide an academic response since all posted on this subject comes back to that simple statement I made. All the other postings are distortions that have run amoke such that nobody knows the subject of debate and it has become a joke. Your input to the statement I am sure from your comments will be academic in form and greatly appreciated. I am winding this thread down now as statement made are being attributed to me which is false and errors are piling up on errors

* I have used NEC professionally and I am aware of some of the lower-cost derivatives used by amateurs. What I stated before does not conflict with

my experience of using NEC - if I were to tip a vertical element then those effects would result; there wouldn't be any general improvement in its performance.

If the program you use shows increased coupling factor in all directions when you tip a vertical monopole then it, and your interpretation of its results, is in error. If you run an 'optimiser' and it yields such a result then the error is widespread in your computing system. The simplest analysis (using arithmetic) of a tipped-over monopole or dipole will demonstrate that its pattern in the horizontal plane is no longer uniform so whatever is gained in one direction is lost elsewhere.

I'm beginning to think that the issue is some kind of arrogance - certain individuals purporting to know better than the conventional wisdom (when they probably don't know much of the basics). But I don't really understand why they do this. Perhaps the volume of responses in this NG is enough to give them a feeling of importance and, I realise, I'm not helping by adding to the bonfire!

Chris

* Fraday rotation is much greater in the ionosphere where there are more
free electrons, apparently. L-band and C-band links with geostationary
satellites use circular polarisation for this reason (as well as others when
a mobile terminal is involved) - the degree of twist is measured in turns.
At Ku-band it's down to a few degrees.

* In the UK, VHF FM radio was launched with horizontal polarisation mainly because of a belief that vehicle-generated nois was predominantly vertically polarised. This belief derived from an experiment, but the conclusion may have contained an error. However, it was clear that VHF reception in vehicles was impaired by this choice because a simple vehicular antenna is vertically polarised. As vehicular reception grew, and when commercial radio started at VHF, a vertical component was added to the transmitted signal to improve matters. Nowadays, most of the transmitting antennas for VHF FM radio provide 'mixed polarisation'.

> polarized rubber ducky antennas. Yet, most laptops have their
> antennas in the top of the LCD frame which are horizontally polarized.
> Same with PCB antennas found on most PCMCIA cards.

* A vertical whip on a device with a horizontal chassis, and horizontal power/data cables, probably radiates plenty of HP as well as VP. Years ago (before the widespread use of normal-mode helix antenna) I worked on a scheme that involved STC/ITT 'Starphone' hand-held transceivers. The base-station antenna was VP but the handsets each contained a PCB loop antenna where the axis of the loop was parallel with the long dimension of the handset, that is, generally wrong! ... but the scheme worked quite well and there was no chance of whip antennas getting broken.

> Anyway, nobody cares much about antenna polarization:

* Well, some still do!

* You haven't cited a reference. The words you have written here do not
demonstrate that EM waves are longitudinal. A 'reference', if you didn't
understand the term, means a passage from a book or paper written by someone
who has a proven reputation for good, useful work in the field.

>>>>Sound waves are longitudinal because air pressure is a scalar, whereas

* What 'two loudspeaker'? If you're drawing comparison between a direct-radiator loudspeaker and a dipole and using that as a basis for saying that EM waves are longitudinal, as I suspect you are, then you should also consider a horn loudspeaker. Sound is radiated from the mouth of a horn 'speaker and the other side of the compression driver diaphragm can be totally enclosed. There is no simple comparison with a dipole antenna in this case.

>>
>>
>>>> Also, antennas that radiate are fed with alternating current. The

> S*

* It's even more interesting to read text books by writers such as Kraus who have known provenance. Maxwell's equations are covered very well in his books 'Antennas' and 'Electromagnetics' - I suggest you read them. It appears a lot of what is published on the WWW is written by people who haven't taken the time to learn the basic simple stuff; school pupils and college students perhaps. You have to be very careful what you accept as true when the internet is involved.

1722. Art's "Tipping" Belief Explained?

Newsgroup: rec.radio.amateur.antenna
Date: 2009-09-06 12:02:20 UTC
From: Richard Fry <rfry@adams.net>
Message-ID: <194de661-9754-43e1-a346-6745a33f997d@o10g2000yqa.googlegroups.com>
Source record: 13434

The link below leads to a composite NEC plot comparing the elevation patterns of a vertical dipole with one that is "tipped."

Sure enough, the tipped antenna has slightly more peak gain, and the elevation null at the zenith above the vertical version is filled -- just as Art has posted.

However the reason for that is NOT that the antenna itself radiates better when tipped. It is the result of directing more of the peak gain of the radiation pattern launched by the antenna (which is a constant regardless of its physical orientation) toward the earth near the antenna. This increases the earth reflection in that direction/ sector.

Those considering only the net, far-field radiation as calculated by NEC may think that the antenna itself radiates better when tipped. But it is only the contribution of the earth reflection that makes it appear so.

The radiation pattern of the antenna itself remains the same, regardless of its physical orientation.

EM radiation waves *are* groups of quantized coherent
particles. It's called the wave/particle duality. If
one is expecting a wave, one detects a wave. If one
is expecting particles, one detects particles. In
reality, there is no difference between waves and
particles which existed long before man evolved.

If you will simply conceptually replace whatever particle
that you believe is blasted off the surface of a radiator
with a photon radiated by an energetic electron that
remains on the surface of the radiator, you will
have the presently accepted standard physics model.

For something resembling your concepts, one might say that
the RF source supplies the energy for the bullets fired
by the electron gun located on the surface of the radiator.
The gun didn't have any bullets before the source supplied
the energy for them. Once the electron gun is loaded,
Mother Nature pulls the trigger.

A photon at rest on a radiator is undetectable if it can
exist at all. The theory is that photons are created by
supplying energy to electrons. Photons are the method that
electrons use to shed their excess energy.

Could it be he means an 'MLB', a Magnetic Longwire Balun?

A small MFJ tuner will do a better job, especially since he
claims he'll only needs it on a receiver.

Note: a 'longwire' starts at abt 5 x wavelength. That's not the
same as a random end-fed wire.

> supernatural forces are involved.

You seem to be missing the fact of physics that mass
and energy are equivalent forms related by constants.

e = K1*m and m = K2*e

where K1 and K2 are constants.

For transmitting, there's nothing to prohibit mass from
being supplied in its equivalent energy form and then
lost from the antenna through radiated mass.

(energy in) = (mass in)c^2 = (energy out) = (mass out)c^2

When an atomic bomb goes off, mass is not lost - it simply
takes the form of an equivalent amount of energy which, if
we were smart enough, could be converted back to mass.

The design impedance of a balun is determined by
taking the square root of (the input impedance
multiplied by the output impedance). Do you know
the output impedance?

Actually, a radiator radiates equally during each
half cycle, i.e. it loses equal mass during each
half cycle.

Hint: think balanced transmission line with its
two equal differential currents. Electrons on the
balanced radiator are accelerated/decelerated
equally in either direction.

The lobe of a full-wave dipole is narrower than that of a 1/2-wave dipole, so the tipped version of the full-wave should show the worse "equilibrium" of the two configurations.

What you refer to as a photon I refer to as a particle
I refer to it as a particle because of the Gauss connection.
One can also use same with a capacitor where the particle
is retained between two diamagnetic surfaces and the
charge may transfer. Would you have it that a capacitor retains
protons which is a particle ?
With my analysis it has a trail but yours seem to be just snippets.

Perhaps you should provide a response to the Gauss/Maxwell thread
where only one academic has come out in favour of David, whereas all
others are unsure of the limits of the law on statics. I consider that
the beginning of my trail, so how does yours differ.
The thread is still there!

But if it is full wave it is a tank circuit which does not radiate in
both half cycles but in pulses
as Planck states. It only radiates when the capacitive field
intersects with a magnetic field.

So you are saying they are one and the same where a wave is a
adjective describing the action of a spining particle. Interesting you
quote the electron gun. We have an electron
without a spin and certainly not with the speed of light. So we supply
a electrostatic field which intersects a magnetic field. When this
electron ,particle proton or what ever enters the area betwean the
capacitive plates. At that time the article (not to take sides)

starts to accelerate under the influence of both fields such that it takes on a parabolic spin.
When it exits this combined field it obviously takes a straight line projection with spin.
Now without the fields influence we move beyond acceleration where the speed can be determined. It is proven that it is a certain speed that was later determined as also the speed of light. So, we have a beam which is certainly not of a wave but a stream of particles which operate at the same speed as light. Very interesting. This moves away from Rutherford wave theory. Along comes the slit experiment which then sways back thought to the wave theory which is a convenient wy of saying it is undecided.
Now we have the slit antenna that sways the argument back to particles which has a connection to light and spin and the acelerration of charge. No where has the propasition of a photons being around is stated. Now you state that a photon exists dependent on the rate of spin to shed light So where did this photon emerge from?
It certainly did not come from mass as that can only happen when the nucleus of an atom is torn apart as you point out with a atomic explosion which is the result of what is called the Strong force and that is not happening. So if you provide an answer to the posted question posed on Gauss and Maxwell we can then follow on to explore your reasoning. But you must start from somewhere that is accordance with accepted laws. I have done that where you have not. So the question posted is salient to this whole discussion and your education suggests you are up to the task so what is it that you are uneasy about?

Umm, no, photons are "particle like" and at the same time "wave like".

Maybe but waves are an adjective where as particle is a noun. Yes a
cluster or a swarm
may move together that has the appearance of waves which also can be
seen as a swarm of particles but again root of discussion must be a
noun. An accelerated beam is that of a single particle action that is
repeated. The particle alone cannot act as a wave unless it has
another particle that can be seen as a datum.

ever hear of electrons changing state and emitting photons? or the
photoelectric effect?? neither require strong force or nuclear reactions.

So the question remains where does a photon come from if it is not an
internal function of a free electron. Frankly the capacitor suggests
that the photon is a charge possesed by
a free electron. So again we are back to the Gauss/Maxwell question.
Cecil does has a track record with his degree and more important his
MENSA membership but he is having problems with the photon. particle
problem which lies with the Gauss/ Maxwell question.
Einstein insinuated that the weak force is part of radiation and I
have applied my theorem to that. But I can't persue other theorems
until the Gauss/maxwell question is resolved by those with a track
record and not just intuition.

go read up on single photon diffraction experiments and see if you still
think it takes multiple photons to act as a wave.

" Oliver Heaviside criticised Helmholtz' electromagnetic theory because it
allowed the existence of longitudinal waves" .From:
http://www.answers.com/topic/hermann-von-helmholtz

Do you know somebody who has more proven reputation in acoustic and
electrodynamics than Helmholtz?
Hertz was the pupil of Helmholtz.
The Maxwell's equations (that from 1864) was the same like the Helmholtz'
for fluid mechanics.
Many textbooks inform us that it was a big Maxwell's mistake. He ignored
atomic nature of electricity disovered by Faraday at electrolise. Helmholtz
not ignored it.
Maxwell (modified by Heaviside) is only a piece to teach the math.

Take a rest in reading and look at the oryginal Hertz apparatus as the two
sources of longitudinal waves (radiated from ends). You should see the
Luxembourg effect (frequency doubling) and directional pattern.

photons have no charge.

>So again we are back to the Gauss/Maxwell question.

separate guass and maxwell. gauss wrote laws, maxwell made a collection of equations and tied them all together... some of which were written originally by gauss. the basic laws that went into maxwell's collection have been well proven separately for over a century, and as a collection to explain electromagnetic waves almost as long. but note that maxwell does not talk about particles, his equations describe fields and waves. They do contain terms for charge, but do not tie it to any given particle... and if you include the force equation then you can talk about mass and charge, but again not tied to any specific particle.

>Einstein insinuated that the weak force is part of radiation and I
>have applied my theorem to that.

ah, so that is where you have crossed up the weak for and radiation... unfortunately the radiation being described in relation to the weak force is not electromagnetic radiation, but rather radiation caused by nuclear decay... most often beta decay where the nucleus emits an electron and converts a neutron to a proton and an anti-neutrino. hmm, do anti-neutrinos cancel out your magical levitating diamagnetic solar neutrinos?

but you don't because that is not how it works. the waves are radiated by
the whole length of the connecting wire and are transverse... there is no
frequency doubling as you explain it.

because art is the consummate Democrat... he thinks that if he believes something then it must be true and its up to everyone else to prove him wrong. just look at the Democrat's belief that throwing money at education will result in better educated students... that has been going wrong for decades and they still believe it. art also shares another quality with Democrats, they don't learn. They keep doing the same things over and over again expecting to get different results... isn't that a thing called insanity?

Hmmmm.
Yesterday afternoon, I graphed the amount of natural light striking my property. I started around 3:00 and measured until 8:00. The trend was alarming! The natural light kept getting lower and lower. If that trend has continued, there would have been no natural light at all by today. Fortunately, the light started increasing again just after sunrise this morning. Wow. That was close.

(Sorry, I couldn't resist.)

Jimmie the answer resides in the question posed. If you have a track
record such as a degree where you can explain academically, place your
input or be declared a follower.
2;1 against me so far but I need a couple more. So far there has been
much more that have commented but I have to sort intuition from
academics to decide on the playing field

Could be I believe Cecil thinks otherwise but first we need to verify
the first statement made to determine what path to take. As yet
photons are not in Maxwells laws as we know it. That is Cecil,s track
without the beginning disclosed or a position on my beginning
and he has a problem with that, hopefully he comes down on my side

>

We are in agreement up to here, a drum roll please!
and as a collection to
> explain electromagnetic waves almost as long.
Nope. He added to the laws dt becau8se the metrics must add up to zero
per Newton
From this addition the metrics supply a clue to accellaration of
charge

 but note that maxwell does
> not talk about particles, his equations describe fields and waves.

Yes but not a explanation of the addition referring to acelaration of
charge dt

Theories alone have come along by others, waves, particles (photons)
and a little bit of both as yet none have been conclusive.

 They do
> contain terms for charge, but do not tie it to any given particle..

Back again we are in agreement

. and if
> you include the force equation then you can talk about mass and charge, but
> again not tied to any specific particle.

Again we are in agreement, this is terrific !

>
> >Einstein insinuated that the weak force is part of radiation and I
> >have applied my theorem to that.
>
> ah, so that is where you have crossed up the weak for and radiation...
> unfortunately the radiation being described in relation to the weak force is
> not electromagnetic radiation,

That is a matter of contention which is why I turned to boundary laws
which exhibit all forces. The one I chose was Gaussion law of statics
to procede upon since it was the basis
for placing a weak force in position which up to that point had not
been applied.
Thus to keep in line with Maxwells laws I was forced to make a static
field dynamic
which is accepted by physics unless I want to make it a special case
as others seem to think

but rather radiation caused by nuclear
> decay... most often beta decay

Well the Sun did provide these particles when equilibrium was broken
so if residue from the sun is radio active OR includes such I can
accept that. No problem

where the nucleus emits an electron and
> converts a neutron to a proton and an anti-neutrino.

I have "hinted" at neutrinos because it is presently hinted that
several typed of Neutrinos (flavors are emited by the Sun) we also see
light on contact with the Aurora but I decided to hang my hat on a
particle/ free electron because a lot can happen between the Sun and
its travels to Earth.

Well now you are into theory and just like the Higgs field all are
searching for conformation
via existing laws to give some substance to particles between the sun
and the Earth!.

 hmm, do anti-neutrinos
> cancel out your magical levitating diamagnetic solar neutrinos?

I have no idea. We do not know what is the difference to flavours
emmitted or their characteristics., What we do know is they enter the
earth as the smallest mass known
(from the Italian world of Enrico)
All of this starts with the Gauss/Maxwell aproach where I say you can
turn a static field into a dynamic field which is against the

perception of those on the group that are educated ,
academically.At least so far as those who are comfortable with both of
these laws.

The NEC computer programs are not in error. The error is in
understanding how far-field patterns develop.

Art, please read the following link about "tipped verticals," which
hopefully will lead to a better understanding of this issue.

I thought you had trackrecord in academics so you had a understanding
of the Gauss/Maxwell laws Oh well we all make mistakes
.
Now for your eznec set up. If it were me I would not quit so early but
at least try to fill a quadrant so you can determine a step that
appears logical
A bit to early to slaughter the messenger tho it appears to be your
intention.regardless

... and the so-called 'Luxembourg effect' is not frequency doubling but
cross modulation; that is, generation in the ionosphere of intermodulation
products that carry the modulation of both sources. Third-order IPs are
usually much more important than harmonics when they fall in the same band
as one or more of the generating signals.

```
* Yes: the late John D Kraus. He was a practical engineer as well as a
theoretician and his native language was English. He managed to put into
practice a lot of the theory that others had written about and he recorded
his work lucidly. I've already named two of Kraus's books - can you cite
something written by any of your favourites that provides clear explanations
that you understand? Answers.com doesn't explain anything technical.

* Heaviside's documentation is appaling! I remember going through a
catalogue of his work in an effort to get to the truth about the origin of
the 'Heaviside condition' - a lot of it was written in obfuscation babble, a
bit like some of the contributors to this group.

The NEC computer programs are not in error. The error is in
understanding how far-field patterns develop.

Art, please read the following link about "tipped verticals," which
hopefully will lead to a better understanding of this issue.

http://groups.google.com/group/rec.radio.amateur.antenna/browse_thread/thread/d419e5b91e29
e0be/a174e9df6d9d1aa9#a174e9df6d9d1aa9

RF

* Richard, thank you for that. I stand by what I have stated in several
places earlier in this thread, that if tipping-over a monopole or dipole
results in more gain in one direction then that will be counteracted by less
gain in another direction (i.e. azimuth) as your eznec pattern illustrates.
There is also the question of polarisation purity.

Chris

If you understood NEC programs and the underlying physical principles on which they are based, Art, you would realize that the graphic comparison I posted represents the BEST CASE for those two conditions. Average performance over a quadrant is even worse.

If you have another "step" that appears logical to you, and which you think proves your point, I'll be happy to model it if you will supply acceptable details.

But from your point of view, you'd have been better off not making such a statement.

Dear Group:
I applaud the suggestion to read my mentor's book on Antennas (any edition) to gain an understanding. The clarity of his writing is the best that I have found. However, recently a collaborator of Professor Kraus has written a small, inexpensive book just explaining Maxwell's compilation of equations.

Consider the purchase and study of: "A Student's Guide to Maxwell's Equations" by Daniel Fleisch. ISBN is 978-0-521-70147-1 The publisher is Cambridge University Press. Amazon has the book for about $23.

Art wrote:
"I thought you had a trackrecord in academics so you had an
understanding of Maxwell`s laws."

Maxwell`s equations are necessary and sufficient to describe radiation from any antenna. I long ago suggested in this newsgroup that Art read a fine book, "Radio-Electronic Transmission Fundamentals" by B. Whitfield Griffith,Jr., now reprinted by Scitech Publishing Inc.

In the first chapter Griffith gives a brief history of electrical knowledge. On page 3 he says:

"We had, for instance, Coulomb`s law, relating to electric charge and the mechanical force it produces; Ampere`s Rule, connecting current and magnetism; Gauss` law, giving the relationship between electric charge and the field of the electric potential; Ohm`s law, relating voltage, current, and resistance; and Faraday`s law, concerning the relationship between the magnetic field and the induced voltage. Nothing seemed to tie these miscellanious relationships together, althoigh they appeared to pertain to the same general subject.

Perhaps it was the working of a fateful pattern, perhaps mere coincidennce, that there was born in the same year that Faraday made his great discovery the man who was destined to correlate and organize all these separate rules into the modern electromagnetic theory."

"Maxwell`s Generalization"

This posting is long enough so I`ll stop.

Best regards, Richard Harrison, KB5WZI

Dear Mike: If you decide not to place wire in conduit, consider the use of PE jackets. Heliax seems to have PE jackets. The animals in Michigan love chewing on PVC jacked wire/coax. You might be far enough north not to have the sort of chewing animals common in Michigan.

My experience with 4 inch conduit (plastic, outdoor) is that one may pull one set of wire/coax while assembling and sealing ten foot sections, and then forget about pulling more wires.

Let us all know what you ended up doing. 73, Mac N8TT

... which I've further clipped (Chris).

* Thank you Mac. A voice of sense in the wilderness!

I'm aware that Fleisch collaborated with Kraus to compile the third edition of 'Antennas: for all applications' classified as ISBN 13: 978-0-07-112240-5 and ISBN 10: 0-07-112240-0. In my view this is one of the clearest editions of 'Antennas' so his guide to Maxwell's equations will certainly be worth investigating.

I found another, rather unexpected, source of lucid practical application of some of Maxwell's equations in a book that may be the 'bible' for those involved professionally in VHF/UHF aeronautical communications: 'Ultra High Frequency Propagation' by Reed, H.R. and Russell, C.M., Boston Technical Publishers, of which I have the second edition from1966. Chapter 4 therein. I bought my copy from one of the on-line second-hand book stores for something like 8 UKP. I recommend it to all who read this news group - it really is lucid on lots of matters of antennas and propagation, and not just at UHF.

Chris

Well Jimmie it is very interesting so far. Two academics who came
forwards
presented a real clue on our differences which allows us to
concentrate on a single factor.
The point that they are making is that this is a rare exception to the

ability of turning a static field into a dynamic field ! This is the single point of disagreement on the validity of the starting of the trail that I undertook. Those two are comfortable with the understanding of Gauss and Maxwell where others were unsure. So the task is now simple which allows others to join in. What in this situation makes it different to other situations that does not allow a transformation to a dynamic field which is the norm of Classical Physics.
Short, clear, and to the point which is all inclusive to the discussion. It wipes out all the side talk and accusation of arragance and the use of the term babble when one cannot understand points made . I am real happy these two came forward because it essentially has high lighted our differences upon which we can concentrate on. What in terms of Classical Physics that is placed forward by these two prevents the change over to a dynamic field? Maybe they will tell us or maybe it is for the individual to identify which and what is correct and why.
Progress at last!
After all these years after discussion between suedo experts shooting from the hip and hitting themselves in the foot.

Dave

This getting to be as bad as the s.p.fusion and s.p.relativity groups.

Heck, Chris makes a lot more sense (s.p.fusion) and actually learns
things, provides results and admits mistakes while he tries to build his
fusion reactor in a London flat. He still claims the govt has
lobotimized him several times and "it grows back", but other than that
he's quite sane. Unlike Art and Szczpan.

Equilibrium is when there is no gain. When this occurs there is
polarisation purity.
Gain is not a factor in equilibrium so why muddy up the question. Or
is that being arrogant
because you disagree with me LOL

Another data point. Or better put, Art's babbling for today.

So now we have

Equilibrium ==

1) no reflections.

2) isotropic.

3) no gain.

Keep going Art.

If I missed one, step in Dave.

Equilibrium is when there is no gain. When this occurs there is
polarisation purity.
Gain is not a factor in equilibrium so why muddy up the question. Or
is that being arrogant
because you disagree with me LOL

* I don't suppose it's arrogant to present reasoning derived from the work of those who have provided practical antenna designs for the masses for a century or more - it's just a case of reminding the readers of this NG what's already out there, freely available for them to investigate (as though most of them didn't already know!).

I do suppose it's arrogant to present new, unproven, possibly paraphysical, attempts at 'explanation' involving poorly-defined terms like 'equilibrium', in opposition to the conventional working and expecting those who read this NG to believe them, when the full working appears to be withheld.

So you say, Art.

Note that a useful and practical antenna with "no gain," i.e., an isotropic radiator, does not exist in the real world.

So what good is your concept of "equilibrium?"

Probably most readers of your posts on this subject (including yours truly) don't wish even to _appear_ to support your stated point of view on this subject, so far.

Still, I suspect that most/all of us are willing to be convinced otherwise, if you can supply any legitimate reason(s) for us to do so.

The next step is yours, Art.

Art wrote:
"Equilibrium is when there is no gain."

I for one appreciate that statement because from my standpoint it is the first intelligible statement I remember from Art defining "equilibrium". If you tip a ground-mounted vertical antenna, you lose "equilibrium" because you disrort its normal omnidirectional pattern. The result is a gain in some directions and a loss in others. Gain and directivity are two sides of the same coin.

Light beams and radio beams are very similiar except light is visible. I`ve seen no gravitational effects on light beams and were radio waves visible, I`d wager you would see no gravitational effects on them either. The same for the Coriolis effect.

Best regards, Richard Harrison, KB5WZI

"Christofire wrote: "Would you care to cite a reference where it is stated that EM waves in the far field of a transmitting antenna contain a significant logitudinal component? Many respected authors, such as Kraus, have illustrated the cintrary."

Add Terman to Kraus. On page 1 of Terman`s 1955 opus Terman says: "Electrical energy that has escaped into free space exists in the form of electromagtnetic waves. These waves, which are commonly called radio waves, travel with the velocity of light and consist of mahnetic and electric fields that are at right angles to each other and also at right angles to the direction of travel."

Szczepan also wrote: You should see the Luxembourg effect (frequency foubling) and directional pattern."

That would interest me. I worked four years in a European shortwave broadcast station and I don`t remember any frequency doubling but we aspired to hit the ionosphere with enough power to drive it into extreme nonlinearity end impose our signal en all the others in the area ala Luxembourg.

Best regards, Richard Harrison, KB5WZI

Oh, yes -- please. I did my satellite dish that way in 1985 and have had no
problems.

> You'll need a 90 degree elbow at each end. Use the largest radius you
> can get away with.

To the OP: A sweep elbow is that "large radius" section. Sweep elbows are
available in various large radii, like 36", and will treat your Heliax or
other cable bends kindly. The plumbing trades use them, too.

This picture shows a half-buried sweep elbow

<http://sugarmtnfarm.com/blog/uploaded_images2009/UGElectric/UGElectPedestal
OpenT6799w.jpg>

It's from http://sugarmtnfarm.com/blog/2009/08/underground-electric.html

The article may provide the OP some tips.

RELATED: With my dish install, I picked too-small PVC and couldn't pull the
whole length. I had to cut the PVC into sections, pull the conduit through
each section (and through new couplings) and then glue the sections back
together. My mistake wasted half a day. Check your "pull-ability" before
gluing your parts into a unit.

It is not new: "If sunspots do go away, it wouldn't be the first time. In the 17th century, the sun plunged into a 70-year period of spotlessness known as the Maunder Minimum that still baffles scientists. The sunspot drought began in 1645 and lasted until 1715; during that time, some of the best astronomers in history (e.g., Cassini) monitored the sun and failed to count more than a few dozen sunspots per year, compared to the usual thousands."

I've often thought I would try a 45 degree elbow, and then a straight
section of pipe coming out of the ground at an angle. That makes it
much easier to pull but does look a bit odd. It also has the
advantage that I might be able to use some manner of power assist to
pull the cables through the conduit. Pulling on a 90 degree elbow is
a sure way of breaking it. 45 degrees can be handled with a pully or
careful positioning of the winch. Disclaimer: I've never done this so
beware of surprises.

>RELATED: With my dish install, I picked too-small PVC and couldn't pull the
>whole length. I had to cut the PVC into sections, pull the conduit through
>each section (and through new couplings) and then glue the sections back
>together. My mistake wasted half a day. Check your "pull-ability" before
>gluing your parts into a unit.

One tower owner had a 90 degree elbow projecting out of the ground
near the outside of the concrete tower pad. He tried to pull the
entire cable bundle through at one time with a winch hooked to a pully
on the tower from above. Instead, he pulled the 90 degree elbow and
about 10ft of pipe out of the ground. I didn't see it happen but was
involved in the subsequent cleanup job.

Moral: Don't let the cable bundle get twisted as it enters the
conduit or it will develop a "lump" and jam.

Tower drivel:
<http://www.agl-mag.com>
It's totally for commerical tower owners, doesn't have anything on
construction, is stuffed with tower politics, but does make
interesting reading. Full issues are downloadable.

magnetism?

>

He corelated not all but only the two. In EM the two exist. We need
eliminate the two from the three.
>

The most important is: "althoigh they appeared to pertain to the same
general subject."

Art is trying to organize them.
It seems to me that he (like many of you) discovered that antennas radiated
something from the ends.
Do you see it also?

You have read too lot. Mike is right: "It's a lot easier to argue these
points without references"

Hertz did not hit the ionosphere. Look at his apparatus:
http://people.seas.harvard.edu/~jones/cscie129/nu_lectures/lecture6/hertz/Hertz_exp.html

You know that "According to theory, if electromagnetic waves were spreading
from the oscillator sparks, they would induce a current in the loop that
would send sparks across the gap."

According to EM theory the frequency is one and no the lobs in directional
patern.

But you can assume that the capacitor plates are the two seperate sources of
electric waves (of course not in phase).
In such case the frequency in the receiver will be its orientation
dependent. But there are only the two possibilities: the same or doubled.
Similar will be with the directional patern. There has place the normal
interference.

Of course the monopole antennas are free from such phenomenon. What are with
dipole arrays I do not know. People from a phase radar know.

Not all vertical dipole exhibit it. The both ends must be above a landscape.
The famous Luxembourg mast was on the tip of a mount.
The Warsaw was on flat so the effect was obserwed only in Austria mountains.

This is only one theory among many (choosen by teachers to teach the math):
"These waves, which are commonly called radio waves, travel with the
velocity of light and consist of mahnetic and electric fields that are at
right angles to each other and also at right angles to the direction of
travel."

Each famous scientist wrote his own Electrodynamics.

look at the plots, when you tip it you reduce the vertical null so you are
making it less directive. remember, the ham 'omnidirectional' use means
only in 2 dimensions... art has taken the leap to 3 dimensions!

Hi,

I have created a Fourier Transform tutorial. It is located here:

http://www.fourier-series.com/f-transform/index.html

It uses interactive flash programs to help you see how the fourier transform works. There are currently 5 flash modules with lots of embedded audio in each module.

The site also includes tutorials on the fourier series, complex numbers, the discrete fourier transform and some radio frequency topics.

1799. Coax Cable Question (Receiving Application Only)

Newsgroup: rec.radio.amateur.antenna
Date: 2009-09-07 12:04:00 UTC
From: Robert11 <rgsros@xnotme.invalid>
Message-ID: <h82srgldt1@news.eternal-september.org>
Source record: 13311

Hello,

A few years ago I ran coax from the attic Scantenna down to a downstairs room for my GRE Scanner.

Hard to remember now, but I believe I did it with the good low-loss LMR 100A from the Wireman Co. with BNC connectors installed.

Have to move things around a bit now, and was wondering for these scanner frequencies, as I need a
patch cable length of only a foot or two, does it really matter what type of coax I use as long as the connectors are, e.g., BNC.

If I use the off the shelf stuff like RG58, is the only consideration the coax attenuation for 2 feet, which I guess would be negligible (assuming BNC connectors on it, though):

Do you agree that this would be O.K. to do, and that I probably would never notice any difference
for a run of only 2 feet, irrespective of what type of cable I would use ? (Receiving only application)

Thanks,
Bob

1801. Coax Connectors Question

Newsgroup: rec.radio.amateur.antenna
Date: 2009-09-07 13:23:40 UTC
From: Robert11 <rgsros@xnotme.invalid>
Message-ID: <h831gs$n1b$1@news.eternal-september.org>
Source record: 13313

Hi,

Great group; really appreciate the help.

Do receiving only.

Have been going around a bit in trying to configure several radios and antennas, including HF receivers and Scanners, with multiple antennas. If I use "good" quality multi-position switches to do it, the $ are getting up a bit.

Since I don't really switch all that often, two or three times a day perhaps, I was wondering about just forgetting the switches and just make a simple plug panel using, I imagine, BNC connectors and coax.

So, what kind of life might I expect with BNC's, plugging and unplugging them ?
They certainly weren't designed with multiple in and outs in mind, but they are kind of
well built, and I imagine they would take a fair amount of usage this way; perhaps ?

Anyone have any experience with this kind of an application ?
What would degrade first in them; the center pin ?

Any better coax connectors for this kind of patch panel usage in your opinions ?

Thanks again,
Bob

Art Unwin wrote:
> What you refer to as a photon I refer to as a particle

So do I. "The photon is the gauge boson for electro-
magnetism." Particles are easier to understand than fields.
According to quantum (particle) physics, everything that
exists in reality is a particle, i.e. everything that exists
is quantized.

http://en.wikipedia.org/wiki/Standard_model

> Would you have it that a capacitor retains
> protons which is a particle?

A capacitor retains electrons which can be collected
on a capacitor plate. (Photons cannot stand still and,
by definition, always travel at the speed of light in
the particular medium. This includes photons in standing
waves.)

"In the Standard Model of particle physics, electrons belong
to the group of subatomic particles called leptons ..."

> With my analysis it has a trail but yours seem to be just snippets.

My snippets are sections from the standard model about
which I will choose to stand on the shoulders of giants.

Tom, no I can't masquerade as someone else. I live near London, I'm not building a reactor (at the moment) and I think I'm quite sane.

The reason I'm here is simply the presence of 'antenna' in the name of the NG but I've been aware throughout my career that this topic is subject to charlatans and cranks perhaps more than any other topic in electronic engineering. That's probably because the majority on non-academics have trouble thinking 3-dimensionally which makes vector calculus very difficult which, in turn, makes Maxwell's equations difficult to comprehend and apply. The fraud squad appear to seize this opportunity and use it as a smokescreen!

The cheap coax switches that Radio Shack used to sell (and may still do)
will do fine. They are 75 ohm if any reasonable impedence instead of 50,
which should not matter at all for reception.

The better ones have 75 ohm dummy loads switched to the unused positions,
it helps isolate them. I use one to swtich between a dipole and satellite
TV box on my computer TV card and there is enough leakage that I don't have
to switch, the satellite box leaks through enough. :-)

Geoff.

> quote the electron gun. ... So where did this photon emerge from?

The electron is the gun, the photons are the bullets.
Quoting Feynman's "QED": "So now, I present to you the
three basic actions, from which all of the phenomena
of light and electrons arise.

-Action #1: A photon goes from place to place.
-Action #2: An electron goes from place to place.
-Action #3: An electron emits or absorbs a photon."

For an RF antenna radiator, the electrons go from
place to place in (on) the conductor in the form
of free electrons. The photons go from place to place
in the space surrounding the conductor. Only the
photons can move at the speed of light from the
feedpoint to the ends of a dipole. Electrons move
hardly at all.

You are correct sir.

Art's equilibrium nuggets.

Equilibrium ==

1) no reflections.

2) isotropic/no gain.

3) polarization purity.

Lmr 100 is some very small (about 1/8 inch) coax. If this is what you used,
almost any coax will have lower loss.

MOre likely you used some of the lmr 200 which is about 1/4 inch in dimeter.
In any case the loss in 2 feet of about anything will not be noticed on
receive. Even a piece of rg6 would be ok in your case. You might even want
to replace the whole run with the rg6 coax even if it is 70 ohm stuff
instead of 50 ohm coax.

1812. Grove Pushbutton Switch ?

Newsgroup: rec.radio.amateur.antenna
Date: 2009-09-07 14:42:48 UTC
From: Robert11 <rgsros@xnotme.invalid>
Message-ID: <h83662$s6p$2@news.eternal-september.org>
Source record: 13324

Hello,

Regarding this pushbutton antenna switch that Grove offers:

http://www.grove-ent.com/SWC01.html
$19.95 SWC01

Was wondering if anyone is using it, or has any opinions on it ?
Sure is cheap enough.

They claim "usable" up to 2.0 GHz.

My application would be HF thru the vhf/uhf scanner frequencies,
BUT Receiving only.

Any thoughts on would be most appreciated.

Thanks,
Bob

BNC connectors can be had for as low as 50 cents. They last a long time if
you are careful and I have many surplus connectors in use. I never bothered
with patch panels, but it would be a natural if you are using Hardline or
1/2" cables up the tower anyway. Heavier coax to N connectors then 2-3 ft
rg 58c patch cables to radios. There are Cable connectors to BNC but you
might want to shop around. It might be cheaper than using N - BNC adapters.
I have never had to replace any connectors, but wear and tear has had me

replace a few patch cables. About once a year I smash a Q tip and soak it in 90% Isopropyl and clean the grunge that gets down in the connectors.

There have been a few radios, scanners, that I have modified with bulkhead BNC females

At one point I was a factory tech for a several HT models and would add crystals and align en masse. The radios all had TNC connectors (Threaded rather than Bayonet) After removing the bayonet shell from the patch cable, it was a quick disconnect for either BNC or TNC. Not particularly proper but fast. In any case Stock BNC is quick and good to 2Gig but I wouldn't put more than 50 watts through them at that frequency.

Just use BNC's and don't worry about it, they will last for ever.
After all almost every bit of test equipment uses BNC's and they endure
multiple connections/disconnections without worry.

Thank you all for your responses. I definitely need to review the best approach. I've gone through a lot to put this tower up and don't need to have a weak link in the system. I'll look into getting conduit that meets electrical code for Alberta. As far a critters are concerned, I have field & deer mice along with voles so to keep this little buggers out, this is the best way to tackle the job. I do have an electrician coming to my home for other upgrades and just may have him work on the conduit piping, too. Time is against me as I have approximately 6 weeks before the ground freezes. Oh yes, I have about 2 feet of beautiful Alberta topsoil before I hit clay. I'll keep the newsgroup up to date with my progress. Once again, I thank everyone for their ideas.

Lousy. The ears on the BNC jack will get worn fairly quickly. Some
of my walkie talkies have BNC connectors for the antenna connector,
all with worn out ears.

>What would degrade first in them; the center pin ?

The two ears on the jack will wear out. The electrical connections
will be fine for many years if you don't care about mechanical
retention.

>Any better coax connectors for this kind of patch panel usage in your
>opinions ?

For scanning, almost any kind of coax switch will work. A mechanical
(not electronic) 75 ohm video switch or IBM 3270 network switch will
do just fine. You'll never notice the impedance mismatch and losses,
except perhaps at 800MHz trunking frequencies.
<http://www.blackbox.com/Store/Results.aspx/search-bnc+switch>
The mechanical switch might also use phono connectors, not BNC.
Adapters are common. Of course, you can build your own.

That's an A/B switch from a dual coax CATV system. The connectors are
Type-F which will require adapters to BNC. The switch is rated to
1GHz and probably works well above that frequency. A more modern
version is commonly available from CATV and Satellite TV vendors:
<http://www.sadoun.com/Sat/Products/Perfect/Perfect_Vision_A_B_Switch.htm>
$5/ea plus tax and shipping.

That's exactly what BNCs were designed for; plugging and unplugging.
Take a look at all the test equipment using BNCs.
The big advantage of BNC over others is the ease on
connecting/disconnecting; they are extensively used in commercial and
military patch panels. Surplus patch panels are often a good source of
excellent connectors.

They are weatherproof, assuming you use good quality ones and not
el-cheapos; and install them correctly. I have used BNCs outside where they
have been in use through more than 20 Canadian winters and when I checked
them each spring and fall were perfectly clean inside - although the outside

showed definite signs of weathering.

The only failures I have ever observed in a properly installed BNC has been the failure of the fingers in female receptacles on cheap connectors used in some consumer devices - especially scanners. I usually take a close look at any BNC on any non-professional device I purchase and if it looks suspect - a good sign is only two fingers in the receptacle - I replace it because the odds are it will eventually fail.
Any BNC connector which doesn't have a name and/or number on it is probably not a good idea!

The only precaution I would take is if you have to leave a BNC - or for that matter any connector - disconnected for any length of time outside is to protect it from the elements. If you don't have a proper protector (they can be hard to find) then put a piece of plastic bag over it and seal it with a ty-wrap. I have just such a spare cable sitting out in the weather for the last 4 years and with two layers of plastic bag material the outer layer was starting to deteriorate after 3 years so I replaced both layers this spring.

Hope this helps.

Almost nobody read this famous. Here is the list:
http://www.df.lth.se/~snorkelf/Longitudinal/node4.html

Time for writting such is over. Now people produce the antennas and do not worry who from giants is right. They use empirical methods.

Each of them proposed the version different from the known. The result is like that:

"In this chapter we have analysed the Ampere electrodynamics and compared it with the Maxwell stress approach. We have seen how these are two sides of the same coin -- one focusing on charge carriers, and the other on the field properties. The forces predicted are of the same magnitude as the well known pinch forces, but act in other directions."

I prefer Ampere - you Maxwell. Nothing wrong.

Huh?

What Richard wrote means he didn't encounter frequency doubling but he did
try to cause cross modulation, as in the 'Luxembourg effect'.

What I wrote doesn't conflict with that.

Perhaps it's a language difficulty on your part.

I like the statement that the electrons in one's house wiring are mostly the same ones that were there when the house was built (or last re-wired).

'Charge' is a funny one though - a bit like debt, it can take effect almost instantaneously (does debt travel at the speed of light - I guess it often does nowadays).

That isn't a cite, that's a formula.

So I guess that you apply the idea that photons have mass.

Never mind.

* No, that's quite wrong. Practical engineers use mathematics a great deal.
Amateurs may not, but they're not all engineers. To make a statement like
that it would appear you have never worked successfully as a practical
engineer using the conventional definition of 'engineer': a person trained
in any branch of engineering.

* It's the passage of charge through conductors, the same as it is
everywhere else, of course. Compressibilty of electrons doesn't feateure in
any of Kraus's books that I've read, which must mean it is not a necessary
concept for normal, physical, antennas and propagation.

> Like fascinating is the two monopoles antennas (your dipoles).
> S*

* You claimed that EM waves are longitudinal, like sound waves, and you used some comparison between a loudspeaker and a dipole as justification. So now you understand that not all loudspeakers behave that way ... so what? Do you still believe EM waves are longitudinal or have you changed your mind? If you believe Dan Russell then where on his site does he state that EM waves are longitudinal? Of course, he doesn't.

On second thought, don't bother replying - this dialogue is going nowhere and is a waste of our time.

Hi

I am specifically looking to consult with (or hire) a NYC lawyer who specifically deals with the NYC Building Department (permit) codes, and knows them inside out.

Realize that some NYS licensed PE's may also have a similar knowledge of the NYC DOB codes, thats ok too.

Lastly, if someone happens to work at the NYC DOB in a similar capacity (code knowledge), that would be great too.....

Had a question with respect to antenna installation (non tower). Need a authorized legal /official response in writing, or advice how to obtain, from Lawyer, PE , or DOB officials.

Understanding that if my question requires a formal payment that is understood and ok.

Please contact me at myles at- DTI dot-- n et.

thanks very much

as long as you keep holding on to the acoustic analogies you will be wrong.
some of the waves 'look' similar, but only because of the poor capability of
computers to visualize time varying fields in 3d.

'Twould appear that way. The concept that materials go away and come back via energy applied to them is interesting. I suppose that the energy applied to an aluminum wire by a copper wire ends up turning the Aluminum into copper, while the power lines turn into whatever the turbine generator's wires are, and the turbine itself eventually turns into steam.

What is old is new again - the alchemists were right!

Absolutely. When the old lady in the flat below bangs on her ceiling with her walking stick, the end of the stick hits the ceiling instantly as she pushes it upwards. Extrapolating, if an incompressible/inextensible rod or string could be made, wouldn't that permit communication faster than the speed of light?

I guess inextensible and incompressible are difficult to achieve, but if either were possible would the communication still be limited to the speed of light?

Nope, the energy in both the tube of marbles and the walking stick
travels at the speed of sound in the medium.

Agreed, but c is finite so is there a degree of compressibility or
expansibility below which faster-than-c communication would be possible? ...
or would the whole principle be scuppered by Lorentz contraction?

Chris

PS: oh dear, I hope no-one applies the Coriolis effect to turn this into
Penrose-Terrell rotation

Egad, not at all.

The elements we use in circuit analysis, for example -- pure resistances, capacitances, inductances, sources, and so forth -- are all impossible to make. Yet we know their properties in exacting detail. One cannot cut a stick to a length of exactly pi meters, yet the properties of pi are precisely known. For that matter, we can't even make a stick that's exactly one meter long, but the meter is very well defined.

Those are just a very few of the vast number of things which are impossible to make yet whose properties are known. Math, science and engineering wouldn't be possible without them.

In the words of the great Basil Fawlty "you'll like this one"!

It appears to be believed, by one or two who frequent this NG, that a tilted monopole provides more gain and somehow 'better' EM radiation than a vertical one. However, we've seen that tilting a vertical monopole distorts its radiation pattern so it is no longer truly omni-directional in the horizontal plane. Then why not create an array of such tilted monopoles, all tilted in different directions, to restore the omni-directional pattern.

The result is a discone antenna, or a discage like the one illustrated at http://gvarc.us/GVARCFrames/Titan/Discone/Launch4life002.jpg. I wonder what the 'new-age theorists' would make of this. Does it require the Coriolis effect to analyse it, or is the old-fashioned version provided by Schellkunoff & Friis(#) still adequate?

>What is old is new again - the alchemists were right!

Hi Mike,

Of late, I have been reading Herman Melville's "The Confidence Man." I won't go into the plot (it strained the conventions of the day - 1850s) but mention one vignette where a kid was hustling two gentlemen on a river boat on the Mississippi. When the kid struck a deal, he sweetened it with a pamphlet on how to recognize counterfeit paper money.

It seems that pamphlets like this wete very necessary back when any bank could print their own bills (something like the great hornswaggle of Wall Street). The banks then had to print pamphlets on how to recognize the exquisite detail work of engraving on their bills so you would recognize the 'real stuff.'

What is interesting is that the counterfeiters wrote their own pamphlets too, describing the exquisite details in their engraving....

He use (probably) the term voltage. Voltage is the same as pressure or the
electron density. Is the voltage the necessary concept or no?
And what about the mass of electrons in the books?

Dan Russel do not state enything about EM. EM waves will be always
transversal because such we assumed before writting the math. Real electric
waves radiated by one monopole end two monopoles you can see on this
animation.
>

The radiation pattern of such an antenna is the about the same as that
of a single, vertical ("untipped") monopole. But for the same
conductor diameter, the multi-conductor, or cage version can have much
greater VSWR bandwidth.

John Kraus has a brief section on such designs in Antennas, 3rd
edition, starting at page 719.

The following link also describes them...

Faster than light communications has already happened.
Entangled particles communicate with each other
instantaneously over any distance. Some say it
proves that reality is non-local but is being
projected from somewhere else. Question is: Who is
running the projector? :-)

I think there are two main avenues of thinking on the phenomenon known
as quantum tunneling being faster than the speed of light. One is
that other dimensions are involved. Data is not traveling faster than
the speed of light, it is just taking a short cut. The other is that
the data was wrong.

It makes a big hole in the old lady's ceiling.

Actually, the energy travels through the building structure at the speed
of sound, not the walking stick, which has energy of momentum until it
hits the ceiling.

In the case of a single monopole mounted with its base at earth level, adding tilt to it makes very little difference in its gain at elevation angles up to +60 degrees or so, at any azimuth. It does partially fill the elevation null at the zenith produced by the vertical monopole, as well as to produce a small amount of h-pol radiation over most of the compass.

Modeling this in NEC for a 1 MHz, 1/4-wave, straight monopole by moving its top 10 meters out of plumb changed its peak gain by about 0.01 dB compared to the untilted version, at any azimuth.

Actually, Art gave me directions for building his 160 meter antenna, the one people call "The Shoebox". SO you're not quite right on that point.

I looked at it, and decided that it very closely resembled an EH antenna, with a tuned circuit on top of some coax. Those type of antennas work after a fashion, probably through feed line radiation in this case. So you could likely build it, install it, and make some contacts with it. Whether that makes it a good antenna is up for discussion. I'd probably go with something else.

Gain has never been as issue in tipping the radiator except for some
who which to interject it.
Pointing's vector shows a radiation patterm that is spherical and in a
state of equilibrium
It is not the radiation pattern of a donut which all are familiar
with. Thus if one wants coverage in all directions one must pursue an
array or conductor in equilibrium.
The present state of the art only considers gravity as being outside
the arbitrary border
such that the equal and opposite vecter is exactly that. ie at right
angles to the Earth's surface. Now we all know that the radiation
pattern of such does not remotely resemble that of Pointings vector!
To get to the point of a spherical radiation pattern one must
recognize that there is an additional vector outside the boundary that
one must consider to obtain equilibrium. So far you have shown
progress by tipping the radiator where it started to fill the void at
the center of the donut. This alone confirms the idea that another
vector has to be considered outside the arbitrary border. Now
rotation is an essential property
of the Universe as fracture of an arbitrary boundary is created by two
forces which are not on a common plane. This is a shear force which
also creates torque or spin ,so it stands to reason that the other
force in combination with gravity is a force of torque or rotation.
If Coriolis is not that vector what other characteristic fits the
bill?

The change in the elevation pattern shape and gains seen in the "tipped" NEC plot I posted are NOT due to equilibrium, vectors outside boundaries, shear forces, torque, spin etc.

The change in the pattern of the tipped vertical dipole are due to changes in the amount and direction of the energy radiated toward the earth by, and near the antenna, and the net field that results by the vector addition of that reflection with the energy radiated in a given direction by the dipole itself.

Suggest you use NEC to model a vertical dipole in free space, at several physical rotation angles away from plumb. See if the gain and shape of the radiation pattern changes (they won't, if your model is valid).

Also note that the Poynting vector does not take the form of a perfect sphere for any linear antenna -- only for a (non-existent) isotropic radiator.

We have now come to the end of my input.
We choose to disagree. I can go along with that
just to get you and others off my back. I will go away
and let all mumble about things between themselves.
I need a vacation this year anyway and the kids are back in school
so it is a good time and the weather is just right.
This month will be momentous at the UN so a seat in the gallery sound
good
We will see.

I just now looked at this link, and see that it states that this radiator configuration is horizontally polarized.

That polarization appears to be "implausible" for this configuration.

Does any scientific documentation exist, or do any measured, real-world performance results prove that this configuration truly is horizontally polarized?

You are so dumb! Look at the center pole as being a vector in
opposition to the gravity vector. Then add the two tilted vectors
which represents the vectors of the Coriolis force.
(Yes, you add both of the vectors for Coriollis because it is a
rotational force) You are then left with a horizontal vector that
balances the above vectors. Thus you have horizontal polarization.
Why? Because the vectors outside the boundary are a combination of
two vectors which is gravity and the Coriolis. Now somebody mentioned
the question of polarization purity ! When you include the Coriolis
effect you get exactly that, a pure horizontal polarization which is
very useful in determining whether forces in shear conditions exist at
airports as views of reflection of transmissions are confusing if
you transfer a mixture in the first place. This way they have purity
in radiation so that reflections are more clearer for their
determinations as to what weather conditions exist and hopefully not
"wind shear" where a plane instantly loses altitude.
You are fortunate that you caught me before I left.

Chris, that's the discone/cage, a transmit antenna with two individual
feedlines from the Radio Room. Some people call it the discage, as on the
website, but I never did.

The cage portion radiates 4 - 12 MHz and the discone portion radiates 10-30.
IIRC, it stands more than 20 feet high.

The antenna I'm trying to remember was receive only and was less than 6 feet
high. It had a shape that sort of resembled a squat wire basket.

Sal,

There's a directory of antennas used at one time or another by the US Navy at http://www.combatindex.com/hardware/hardware_sensor_main.html. Could it be the AS-2231? The 'discage' appears to be the AS-2802. Also, a contributor to this group, Richard Clark, has some photos at http://home.comcast.net/~kb7qhc/antennas/navy/.

I was aware that the discage in at least one of its incarnations had two separate feed lines, and the combination of two antennas in one 'package' gives rise to its particular shape. However, it has always intrigued me that a single element of similar shape has been used since the early 50s by the British Navy in the AJE/UK-SRA-102:
http://middle-watch.com/communications.htm and
http://rnmuseumradarandcommunications2006.org.uk/AJE.pdf. This could be a coincidence or it could be that F. A. Kitchen, the designer of the AJE, had been influenced by having previously seen a discage (his paper about development of the AJE doesn't really explain where the shape comes from). So I wonder when the AS-2802 'discage' came into use?

In this book:
http://books.google.pl/books?id=f3asJreno0YC&pg=PA220&lpg=PA220&dq=long-wire+traveling-wave+antennas.&source=bl&ots=06br76iFKO&sig=ckX_KlwUcZtJrINE73VACALqw-E&hl=pl&ei=wKKmSqHvM8eK-Qa7_8TGCA&sa=X&oi=book_result&ct=result&resnum=1#v=onepage&q=&f=false

no equations, no terms like transversal and so on. Sometimes the Authors
include a math theory. Each math theory has some simplifications. In nature
not separate transverse and longitudinal waves. The math is separate.
Maxwell was the genius. He made the ether model as a solid body. For Him it
was very easy. He also wrote 60 pages of equations for the Saturn rings. He
was also able to write a math for liquid or gas ether. But he lived too
short.

I wanted to know if radio people observe the frequency doubling when
receiving signals from a dipole. It should be easy to check it.
For me is enough to know (from this Group) that such was observed and is
known as the Luxembourg effect.

No, that's called a sleeve, I think, but I moused over the MIL nomenclatures
and looked at each picture. The antenna I was thinking of is the
AS-2866/SRR. I am surprised to see in the write-up that it's only 24 inches
tall. I thought twice that.

I used that website many times when I was working (prior to June, 2007) and
was wishing I had saved the link on my home computer. Now I have it again
:-)))

I think it was removed from USS Dubuque (LPD-7) during the ship's overhaul
in 1982/83. I was there but the memory gets a little hazy about such
details. If that recollection is correct, it predates the 1980s.

You are so dumb! Look at the center pole as being a vector in
opposition to the gravity vector. Then add the two tilted vectors
which represents the vectors of the Coriolis force.
(Yes, you add both of the vectors for Coriollis because it is a
rotational force) You are then left with a horizontal vector that
balances the above vectors. Thus you have horizontal polarization.
Why? Because the vectors outside the boundary are a combination of
two vectors which is gravity and the Coriolis. Now somebody mentioned
the question of polarization purity ! When you include the Coriolis
effect you get exactly that, a pure horizontal polarization which is
very useful in determining whether forces in shear conditions exist at
airports as views of reflection of transmissions are confusing if
you transfer a mixture in the first place. This way they have purity
in radiation so that reflections are more clearer for their
determinations as to what weather conditions exist and hopefully not
"wind shear" where a plane instantly loses altitude.
You are fortunate that you caught me before I left.

None of that sounds very plausible.

What little experience I have of Racal Antennas would suggest they'll be
keeping the details proprietary, but there are some clues in the words of
their advertisement. A 'delta travelling wave antenna' is like half a
rhombic and deltas (i.e. 'V's) can be seen amongst the rigging - horizontal
ones and upward-tilted ones (as well as vertical ones, but they're probably
not driven differentially). A delta supports waves that have the electric

field developed between the two wires so a delta in the horizontal plane would yield horizontal polarisation.

However, the drawing doesn't make it obvious which pairs of wires are driven as the deltas, particularly when there appear be eight legs in the outer ring and three in the inner ring. The words say there are three 'pairs of delta travelling wave antennas' which probably means three deltas, that is, three pairs of wires driven differentially - clear English was never their strong point.

Googling 'difan' didn't yield anything useful so this may be Racal's own design.

Hi,

Was wondering where you folks order small quantities of made up coax assemblies, adapters (such as SMA to BNC) and the like from ?

Grove and Universal always seem to have only about 75% or so of what i need in stock.
Deliveries from the Wireman the last time I ordered, about a year ago, were pretty long.

Any good source(s) for these kind of things that usually have them in stock ?

There are zillions of sources, apparently, if you do a Google, but i was wondering if there are any you guys use that you know are really good and stock a large and divergent supply of these types of things ?

Thanks,
Bob

Frequency doubling can occur in non-linear systems.
Every powered transistor stage has a certain degree
of non-linearity. A passive antenna system is usually
linear.

The "donut" is a red herring. It's a visualization, not a blob of RF coming off the antenna. All antennas radiate in all directions. Some directions are higher intensity than others, but all directions none the less. The donut just exists to help us put a number on what is happening.

So Coriolis needs re-defined also as not a mechanical *effect*, but as an electrical *force* that compels objects or energy to rotate.

I'll not be so beholden to summarily reject what you are saying, but what you are talking about wold have to be something other than Coriolis effect, it would have to be a as yet undefined and un named force.

If you really need "small quantities", then consider do it thyself.

Stock up on an assortments of connectors, a few crimpers:
<http://802.11junk.com/jeffl/antennas/Misc/slides/crimpers.html>
and a thermal wire stripper:
<http://www.teledyneinterconnect.com/products/wire_strippers/wirestrip.asp>
Crimpers cost about $35/ea. A used thermal stripper is about $50 on
eBay. RF Industries connectors are $3/ea to $7/ea. There are plenty
for sale from other vendors on eBay. I stock LMR-100, LMR-240,
LMR-400, and the usual RG-6/u and RG-58/cu for CATV and jumper cables.
For the hams, I grudgingly stock UHF connectors, but most of my stuff
is SMA, RP-SMA, RP-TNC, BNC, and Type N.

If you do more than a few LMR-400 cables, consider investing in a $25
stripping tool such as:
<http://www.jefatech.com/product/T400STRIP/Low_Loss_400_Strip_Tool.html>
or an overpriced version:
<http://www.jefatech.com/product/T400PREP/Low_Loss_400_Connector_Prep_Tool.html>

Buy a supply of shrink tube and a heat gun for a professional look
(and to hide the mess).

I have a TDR for testing long cables, but an ohms-guesser and pull
test are usually good enough for checking just continuity and for
shorts.

Whether this is an economical solution depends on how many cables are
in a "small quantity" and how often you need to make them.

Sound waves propagate in conventionall matter form (gas, liquid, solid).
They always have the two components (transverse and longitudinal). In
practice is the full analogy acoustic waves - electric waves.
It is not easy to to describe the aether. But it exists in common term "eter
waves". The ether waves are artifically produced and for this reason we know
more about them. To produce them we do not need to know if they are electric
or EM.
After some time will be clear which vision (Ampere or Heaviside) is in
agreement with practice,

You are saying about frequency changing. Are many ways to decrease a
frequency and a few to increase. Doubling is a special case of increasing.
In the Luxembourg effect no frequency doubling in above sense. All antenas
radiate in complex way. It is also obvious that it radiate from different
parts. That radiation from different parts may be not in phase at the
receiver. They may be in the opposite phase (like for dipoles). Here is the
key. Opposite phase means also the two pulses in one cycle. Each receiver
has its own resonant frequency. In the result long waves were received as
medium waves with the twice more frequency. There were no doubling in your
understanding.

I use RF Connectors <www.rfindustries.com> They have a bunch of pre-made
assemblies that are very reasonable, and can custom build what ever you
need. They also can supply Part 15 Reverse Thread, and Reverse Gender
Connectors, Adapters, and assemblies. I have used them for years and they
have ALWAYS shipped on-time, and never a failure, or quality concern.
I am just a very satisfied customer.

If you are saying that propagation of sound and radio are the same, you'll
have a lot of work to make me believe that.

You have no understanding about how two signals combine at an antenna.

> Each
> receiver has its own resonant frequency. In the result long waves were
> received as medium waves with the twice more frequency. There were no
> doubling in your understanding.

You really need to understand the difference between linear systems
and non-linear systems. Do some reading to understand how two signals
interact in each type of system.

Once you understand the math (yes, it IS important), you may see how cross
modulation occurs.

obviously that isn't an engineering text, that is a handbook similar to the
arrl antenna book, it looks like it presents very basic theory and practical
design equations. go read kraus or jackson for real engineering education
texts on electromagnetic stuff.

no we don't. and yet, it would be painfully obvious here running
multi-operator in contests with harmonically related bands. it just doesn't
happen the way you are dreaming.

from the description and that line drawing i would guess that it is a
combination of delta loops, maybe looped around twice, and probably fed at
the connection point at the bottom of the mast. that would make them
horizontally polarized.

Thanks for your opinions, "Dave."

But as per my first post about this physical configuration, does any scientific documentation exist, or do any measured, real-world performance results prove that this configuration truly is horizontally polarized?

Maxwell PROPOSED the EM model of aether. All teachers use it to teach the
math.
The "very basic theory and practical design equations" are based on the
electron behaviour.
In EM no electrons which are compressible and have the inertia.
Do you belive that the "displacement current" exist?.
It is the result of ASSUMPTION that electricity is a incompressible massless
fluid.

And you tell us that radiation from monopoles antennas is polarised.
There was a topic polarisation. In wave area is term alignment when we have
the two sources. Aligment of "dipoles" not means that waves are
"transverse".
In the reality no transverse waves. Waves appear in compressible medium. All
waves are the "pressure" waves. In math you can assume incompressibility.
But we here NO.

Yeah, you beat me to the punch........

Now if i might digress a moment, with a situation that is a little similar. I had a colleague who had some odd ideas about other things propagating.

bodily function alert!

His idea was that farts were little bits, particles if you will, of fecal matter that propagated out of one's posterior and transported themselves to other people's noses. Dunno if those particles had any spin tho'. I will allow other readers to determine if any similarities exist here.

On Sep 10, 5:35 am, Szczepan Białek <sz.bia...@wp.pl> wrote:
> And you tell us that radiation from monopoles antennas is polarised.

S*, you might want to conduct a simple and practical test of your belief for yourself, to learn whether or not it is true.

A great many/almost all MW, AM broadcast stations use an antenna system comprised of one or more vertical monopoles. Such vertical-only polarisation greatly reduces the propagation loss for the ground wave, and so increases the ground wave coverage area -- whether or not a MW station has a directional radiation pattern in the horizontal plane.

Such was scientifically investigated and scientifically proven many decades ago. This reality is _very_ important to the commercial success of AM broadcast stations.

Most compact, and inexpensive MW AM broadcast receivers use an integrated, ferrite core "loopstick" receive antenna.

When such receivers are oriented with their control legends and displays aligned in the horizontal plane, as when the bottom/back of the receiver is sitting on a table, they respond most efficiently to vertically-polarised electromagnetic waves.

THE TEST:

Using such an AM receiver and physical setup, tune to a moderately-powered, omnidirectional MW broadcast station located at least 20 km away from your receive location. Then rotate the receiver 360 degrees around its vertical axis.

With no co-channel signals, you will find that the received signal-to-noise ratio for that station goes through two, distinct nulls corresponding to the physical orientations of its receive antenna that are 180 degrees apart, and along a line of sight from your receive location to the location of the transmit antenna.

This result demonstrates that such radiation is (vertically) polarised.

Two vertical monopoles not in phase are like one horizontal dipole. In phase
are like two sources.

>Such was scientifically investigated and scientifically proven many
decades ago. This reality is _very_ important to the commercial
success of AM broadcast stations.

>Most compact, and inexpensive MW AM broadcast receivers use an

When the two sources work the receiver must be propery "algned" (physically
oriented).

>THE TEST:

>This result demonstrates that such radiation is (vertically)
polarised.

If two sources work, interference take place. Equipments are "polarised" not
waves.

I have not possibility to "conduct any simple and practical test". In the
other topic you wrote: "Only thing is that my plots are based on 1/2-wave
antennas." If it means that you have possbilities to measure a directional
radiation pattern then do such:

The TEST:
1. Measure the pattern for a declared frequency,
2. Measure the pattern for the doubled frequency,

Tell us the findings.
Already I have proposed it to Wim. Now I am proposed it to all of You.

If monopole radiate from wire (many sources in line) without tipping there
is a pseudo-polarization.
For this reason tipping is sometimes used.

One wave is not polarised. The two pressure waves from the two sources
interfere. See "Directivity and phasing".
>

"This fourth edition blends, in Joseph J. Carr's words, "the theoretical
concepts that the engineers and others need to design practical antennas,
and the hard-learned practical lessons derived from actually building and
using antennas -real antennas, and the hard-earned practical lessons derived
from actually building and using antennas - real antennas made of real
metal - not merely theoretical constructs on a blackboard."

Now is the electronic era. Electronic is from electrons. They are
compressible and have the inertia. You all construct antennas where
electrons build up voltage. But on the blackboard are math for
incompressible fluid. Look at the famous equations - there no voltage at all
(only current).
If somebody do math for electrons then such math will be on the blackboards.
But it is not necessary. The beautifull EM equations are the same like for
fluid mechanics. They will be saved. Radio engineers do not use them and can
wait for the proper ones the next centuries.

no it isn't. you are obviously way out of date. stop looking way in the
past for theories that were obviously disproven decades ago and look at
modern texts to see which ones have survived 100+ years of experimental
evidence.

>Look at the famous equations - there no voltage at all (only current).

in any electronic system you really only need voltage OR current, they are always related by the impedance. So if you read modern texts you will often see that they derive equations in either voltage or current form then show the other form for reference, or sometimes leave it as an excercise for the student.

no, real engineers are trying to educate people like you who are stuck in the past with outdated theories and simplified misconceptions... or we could just ignore you and hope you go away quickly. personally i think it is more fun to watch what comes out of the mouths of babes when you tickle their feet.

The net, far-field radiation of two vertical monopoles in a directional array driven by one transmitter using a power dividing network is vertically polarised -- because both monopole sources are vertically polarised.

This type of array is commonly used in commercial AM broadcasting, and its characteristics (including its polarisation) have been accurately known for many decades.

Source record: 13271

Just picked up a disassembled 3 element CushCraft beam.
I think its a 10-15-20 meter beam, but not certain. There are
traps (TB-1) on all 3 elements (6 total). The boom was
missing.

Hoping to identify the model so I can get assembly instructions
and length of the boom. No luck with a net search.

Since MFJ bought Cushcraft, the new (mostly empty) Web site is

http://www.cushcraftamateur.com/

with the manuals at

http://www.cushcraftamateur.com/manuals.htm

Maybe you can go through the manuals for the tri-banders 'til you find
something that looks familiar.

1911. Question on re-radiated field

Newsgroup: rec.radio.amateur.antenna
Date: 2009-09-11 15:41:00 UTC
From: Antonio Vernucci <vernucci@tin.it>
Message-ID: <4aaa6f8d$0$822$4fafbaef@reader5.news.tin.it>
Source record: 13273

Can someone please confirm or deny the following arguments.

Let us have:

- a transmitting system operating at any given frequency
- and a metal bar, located far away from the transmitter, whose electrical length is exactly half wavelength at the operating frequency.

An induced RF current will flow in the bar. Such RF current causes a re-radiated field which adds up to the field generated by the trasmitter.

Two questions:

- which are the amplitude and phase shift of the re-radiated field with respect to those of the field generated by the trasmitter? My instinctive answer would be same amplitude (in absence of ohmic losses) and 180 degrees. The total field (transmitted + re-radiated) at the metal bar would so be zero.

- how does the total field change moving away from the bar? I would say that while the field generated by the transmitter varies very slowly with the distance from the bar (the transmitter is assumed to be very far away), the re-radiated field varies fast (also because one would initially be in the near field). In conclusion, the more we move away from the bar, the lower is the contribution of the re-radiated field to the total field. That should be the reason why, in a Yagi antenna, a parasitic element cannot be put too far away from the driven element.

Thanks and 73

I am in the process of adjusting and installing an MFJ-1775 multiband dipole. I would appreciate any comments or useful advice from other users before I proceed to the installation. Some of the concerns I have are:

- Should I cover the inductors to protect from the weather (rain, ice)? If so, how?
- Should I take any other precautions to strengthen the antenna or protect from corrosion?
- I have heard some users have burned up the inductors with only a few hundred watts. Comments?
- Any other...?

1914. Spherical radiation pattern

Newsgroup: rec.radio.amateur.antenna
Date: 2009-09-11 16:47:00 UTC
From: Art Unwin <arthurunwin@gmail.com>
Message-ID: <6dd848d7-9fe4-461c-bf4f-ade1f9c8daf0@h13g2000yqk.googlegroups.com>
Source record: 13276

There has been some "talk" that the spherical radiation pattern shown via Poynting's vector is impossible or just a theoretical thing. There are many things that point to this such as point radiatiion as well as not being a realistic concept. I offer the following as an opposite aproach for the news group.

First, I rely on the basic radiator as being in equilibrium which naturally points to a full wave length or reference to one period. Secondly, I point to a radiator as being the circuit of a tank circuit which is essentially perpetual motion if one removes the frictional aspect.
Thus the approach by Maxwell is the ultimate point of maximum efficiency where all forces are accounted for and ALL contribute to radiation.
From the above it is natural that a radiator is tipped to equal the outside vectors of the arbitrary boundary which are gravity and the Coriolis effect.
We then have to allow the radiator to have near zero resistiveness such that all input power is used solely for radiation (super cooled I suppose)
From this approach we can state that, in the limit of zero resistance all power is converted into radiation! Thus if we have a radiator of one WL
that is tipped in space and of near zero resistance in the impedance metric we will then attain a spherical radiation pattern as with Poynting's vector and thus a demonstration of point radiation together with further evidence that radiation is of a particle and not one of waves.
By the way, since the phenomina of radiation is created solely by the electo-magnetic and electro-static fields per the tank circuit it becomes very clear that radiation is not continuous but in "packets or "pulses" because of the momentary stop as shown at the center of a sine wave.
When I get back I look forward with interest how the group tries to counter above with presently known facts or the common retreat to insults or just rest comfortably assured that the prior postings explain all.
See you all later and have a great week end

Sounds about right. The electric field tangential to (i.e. parallel and
close to) the surface of a good conductor must be small, otherwise a current
would flow in the conductor which would tend to 'short out' the E-field, but
an electric field normal to a conducting surface can have any value ... of
course. A short conducting bar, rotating about an axis normal to its
length, can be used to measure the radiation pattern of a large antenna by
transmitting through the antenna and inspecting the signal reflected back
down its feeder.

Interestingly, even a matched dipole antenna re-radiates a signal - the
amount of power 'dissipated' in its radiation resistance. This is mentioned

in Kraus 'Antennas'.

Quoting from John Kraus' well-respected textbook "Antennas For All Applications," 3rd edition, page 74: "Although the isotropic source is convenient in theory, it is not a physically realizable type. Even the simplest antennas have directional properties, i.e., they radiate more energy is some directions than in others."

The Poynting vector does not apply only to isotropic sources. Here is a link to a simple definition: http://www.britannica.com/EBchecked/topic/473461/Poynting-vector . It doesn't have to describe a perfect sphere. And in fact for practical, physical antennas it never does so.

FYI, Art, nowhere in that textbook does Kraus write anything about your equilibrium, tipping, Coriolis effect, or tank circuits, or their being germane to the proper understanding and/or functioning of antennas.

maxwell's equations have nothing about gravity, the weak force, or the
strong force, or efficiency included in them...

> From the above it is natural that a radiator is tipped to equal the
> outside vectors of the arbitrary boundary which are gravity and the
> Coriolis effect.

the Coriolis effect is not a vector nor a force, it is a method of
explaining what someone on a rotating sphere thinks they see... purely a
figment of your imagination.

> We then have to allow the radiator to have near zero resistiveness
> such that all input power is used solely for radiation (super cooled

Most hams know that a vertical antenna creates a radio wave with vertical
polarization and a horizontal antenna creates a horizontally.

The both antennas (transmitter and receiver) should be aligned. You wrote:
"Most compact, and inexpensive MW AM broadcast receivers use an integrated,
ferrite core "loopstick" receive antenna.

When such receivers are oriented with their control legends and
displays aligned in the horizontal plane, as when the bottom/back of
the receiver is sitting on a table, "

It means that the waves are horizontaly polarized. Next you wrote"

"they respond most efficiently to vertically-polarised electromagnetic
waves." I assume that it is a small mistake.
The following is known for many decades:

One mast is omnidirectional. The two are directional like a horizontal
dipole. For this reason "This type of array is commonly used in commercial
AM broadcasting".

I wrote: "The TEST:
1. Measure the pattern for a declared frequency,
2. Measure the pattern for the doubled frequency.

Some clarification is necessary. The doubled frequency should be set on a
receiving/measuring device.
Each mast radiate omidirectionally. The radiation of the array of the two
interfere. Also in some places it may be received as the doubled frequency.

David
The idea is accountability for all forces. If you model for 100%
radiation without losses you get a spherical pattern, no doubt about
it. With respect to the choice of a WL radiator this is because it
represents a period which classical physics demand.
If one chooses 1/2 WL then you are using a fudge factor since one
cannot avoid overshoot or the use of time just to obtain an impedance
that mankind feel is better.
Overshoot is a matter of correction by a circuit with the correction
getting smaller and smaller but always with the inevitable corrections
This then allows the cross over point of a sine wave to aproach, but
never arrive, at the center representing a 1/2 WL.
Now I have modeled the above aiming for zero for a resistive value in
the impedance
because that is the way programs are set up ,which is fine by me, as

it supplies a truly spherical pattern just prior to the pattern moving away from a transmit to a recieve function
On a separate note. Just because something is not mentioned in a book does not provide mention of such points to be false, only to the fact that the author has not fully completed his studies. There is no such thing of a book that explains all in it entirety, only different versions of plaguerisation,
Failing that it shows that the ham fraternity considers "all is known" about radiation and complely discardes the notion of current possibly being ABOVE the surface of a radiator
when the environment allows it to happen or even the presence of negative impedance with respect to a element with a time varying field e.t.c. otherwise it would be mentioned in a book Ofcourse there will be protests that
certain things such as zero resistance cannot be otherwise electrical laws will have to be modified! Well that has proved to be normal when looking at history so shall we suppres it?

Not so. The receive antenna I described responds to the magnetic field, not the electric field. In an EM wave these two fields are at right angles to each other, and to the direction of travel.

The polarisation of a wave is given by the physical orientation of its electric field. If that field is vertically polarised then the receive antenna I described will receive maximum (magnetic) field, and my experiment will prove that the incoming EM wave is vertically polarised.

> One mast is omnidirectional. The two are directional like a horizontal
> dipole.

However a horizontal dipole radiates horizontally polarised waves. A directional MW array radiates vertically polarized waves, regardless of the shape of its azimuth pattern.

That appears to be true. However I have always used Bernollis
experiments with liquid as being synonamous with current flow. So to
mention Bernolles findings to the question of Eddy flow appears to me
to have some merit., Introduction of pressure in both liquids,
current flow and air flow I would consider having some merit.
I once mentioned the similarity of a mechanical pump which is designed
around Bernollies experiments producing the same deflections that we
see with changing cross sections
of electrical conductors, which then must produce cavitation and thus
eddy curwrents.
Roy instantly pushed me aside on that one saying the functions are
different which immediately declares the Standard forces theory as
nonsense. (Sorry about that Einstein)
Gotta go. Excuse me plse

I did, see the link below.

The pattern of a full-wave antenna is far from being spherical.

... and when you get back, let's see some proof that all this wacky
'new-age' theory is of any practical use to mankind.

I'd be willing to bet, say, 100 UK pounds that Professor Unwin can't create
an antenna in hardware that radiates isotropically, that is, over a whole
sphere within, let's say +/-1 dB with respect to any chosen (but constant)
polarisation. Anyone wish to up the ante?

Chris

I'd be glad to, but there's no way to prove it. Measurement accuracy and repeatability just aren't that good, especially if you're trying to do a full 3D measurement. The closest I've seen to a 3D measurement system actually measured just one hemisphere. It was at what used to be NRAD (Naval Research and Development center) and before that NOSC in San Diego, consisting of a large (100 foot diameter if I recall correctly) rotating circular platform with a semicircular arch overhead. By rotating the platform and moving the detector along the arch, a full hemispherical measurement could be made. The models were physical scale models of Navy ships having appropriately scaled antennas. Even then, though, engineers there told me that when the measured results differed from NEC computer model results, they tended to believe the computer results. It's extremely difficult to make highly, or even moderately, accurate field strength measurements.

A while back I designed an antenna for a consulting job which was simply a two-sloping-radial ground plane made with fairly wide traces on a low-loss PC board. George Brown, the inventor of the ground plane antenna, had observed an omnidirectional pattern in the horizontal plane with only two radials, but the marketing department at RCA insisted on adding two more to make it look symmetrical before selling them. Hence the ubiquitous 4-radial design. (The pattern of the 4 radial version is more circular above and below the horizontal plane, but not by a whole lot.) Anyway, I was concerned that maybe the PCB or the relatively wide, flat conductors might have a detrimental impact on the pattern circularity, so I took it to a local lab that has a high quality anechoic chamber and ran the pattern. When the plot was finished, the lab technician muttered "Holy $/!%", hit the print button, grabbed a camera, and ran into the chamber to take a picture of the antenna. Then he went around to the other folks at the lab with the picture and plot. Seems that it was circular within about a dB, better than their $10k reference antenna. The prototype, by the way, was made with adhesive copper tape and an X-Acto knife and looked as crude as it was. I can't

claim that the pattern was really better than their reference antenna because small differences in positioning of the feedline (even though decoupled), the antenna, and anything else in the chamber can easily cause a couple of dB of pattern deviation.

Forgot to mention.
Current would not be applied to the radiator itself but only to the sheathing
of homogenous particles at rest.(ie neutrinos who are part of the family of Leptons but still remain as particles) This way with opposing forces in shear which includes the bending moment or twist of the Standard Force, the chemical adhesion is broken and the particle is elevated to achieve a straight line projection with spin. In this event all electrical laws lie
intact and where the resistance is solely of that of radiation to which current is applied.

Interesting stuff. I think one can get a good idea what's going on by measuring in the cardinal planes and some 45 degree cuts. It would soon become apparent whether the antenna warrants closer inspection.

I recall seeing what you describe at NRAA and NOSC also at ASWE in Funtington, near Portsmouth GB. There they also had an aluminium 'sea' and copper scale models of most of the British fleet for checking the ELF to HF patterns (scaled conductivities). For the case in hand, though, there's no requirement for a ground plane (viz. 'spherical' in the title) so the resulting hardware antenna could be oriented in a number of different ways and rotated about a single axis for measurement. I've had experience of doing this with a Lindenblad array, and measuring axial ratio at the same time. I've also been aware of someone else's model, made using flexible PCB material formed into a cylinder, which outperformed the brass-tube-and-rod one we were working on!

Feed-line radiation can easily be overcome by using a small oscillator and battery: tiny, stable ones are available nowadays. I'd be convinced if the protagonist managed a truly isotropic pattern at just one frequency.

Hi Steve,

I'm no expert on Cushcraft, but a quick look at the few manuals that I
have on BAMA turns up only one beam that uses the identifier "TB-1"
and that is the three element A3WS duo-bander for 12 and 17 meters.
You are welcome to download the manual from either the main BAMA site
at http://bama.sbc.edu or from the mirror site at http://bama.edebris.com
The other Cushcraft beams that I looked at had two traps on each
element half if they were the 10-15-20 mx variety. Hope this helps.

73,
Ken - K4XL

Maxwells laws are all about accountability for ALL forces involved. In
non diamagnetic materials one cannot account for energy that provides
hysteresis losses.
Thus equilibrium cannot be quantisized.ie balance of vectors. If the
energy movement or decay per unit of time can be resolved then
Maxwell's laws can be modified to include losses, such that all
forces are accounted for. Until then Maxwells laws are governed by
diamagnetic materials used as radiators as they do not retain
hysteresis energy. As for "magic" one only has to play with magnets to
see evidence of elevation together with the undeniability of twist. I
welcome from you an alternative action that arises with a different
application that deviates from The Standard Model per classical
physics. As for Neutrinos,
I prefer to allude to them as particles and not Leptons which
describes particles emitted from the Sun. Unlike Cecil I cannot
explain any properties that they gain or lose or what ever on their
journey from the Sun.(Protons) Thus I am comfortable with the term

"particles" which do not suggest that "neutrinos" cannot and do not change properties during their journey.
Especially in the light of present thinking at CERN that such particles can penetrate to the other side of Earth when they cannot even break the glass of a CRT which they impinge upon.

Hi Chris,

Half-Isotropic (if you allow for total field - you didn't specify and
any protoplasm could game that loose specification) at:
http://www.qsl.net/kb7qhc/antenna/Inverted%20F/Sheet-1%20Field.gif

The design has been kicking around for 10+ years now at that link, and
not even original when I posted it.

As for gaming the lack of polarization spec, I might simply offer that
it doesn't matter - if you use an isotropic detecting antenna to
measure the field of this antenna model in the link. For that
isotropic detecting antenna, I would offer a golf-ball lump of coal
and a thermistor.

You are so dumb that you need help!
If you are going to change the orientation you must change the length
of the radiator
so that is still resonant. ala a state of equilibrium
You did not do that!.
You are proposing that a resonant full wave dipole does not change
its characteristics
even if it falls over. I assure you that you are wrong
Think and think and think about it during my absence and then do your
work over again. Do this before I return so that you may measure the
reactions of your counter parts.
And remember, the tilt and length of the radiator is proportional to
that of the Coriolis vector. No more and no less, if you are going to
abide by the laws of Newton.
I may take my laptop with me as you are not alone with your dumbness
and neglect of the laws of physics. If you are going to suggest some
thing new it must correlate with existing laws of physics. If not you

must prove why such law should not be considered valid Nothing that I have stated with respect to radiation does not violate any existing laws of physics otherwise all would be typing in unison in response. To make believe such a trail that agreed with all laws is no more than a fairy tale is certainly beyond my capability. Only a trail that extends along the line of known laws could have such durability that has lasted and continues, for so long. Again, for every degree of tilt you must correct the length of your full wave dipole or retake your novice examination.

Which one "survived 100+ years of experimental evidence." The
incompressible fluid or the elcctrons. The both have 100+ years.
At first were the two fluids (positive and negative). Poisson made the
beautiful math for them.
Next Aepinus and Franklin propose the one fluid (negative). Maxwell made the
Math for it. Fluid was incompressible and massless.
Next electron were discowered. Charges witch mass and inertia.
>

MW has about hundred meters. Is impossible to place normal dipole. The
helical wound antenna is used. The rules are the same like for normal
dipole.

> In an EM wave these two fields are at right angles to each other, and to
> the direction of travel.

>The polarisation of a wave is given by the physical orientation of its
electric field. If that field is vertically polarised then the
receive antenna I described will receive maximum (magnetic) field, and
my experiment will prove that the incoming EM wave is vertically
polarised.

Fields are the math. I am writing about real observations.

> One mast is omnidirectional. The two are directional like a horizontal
> dipole.

>However a horizontal dipole radiates horizontally polarised waves. A
directional MW array radiates vertically polarized waves, regardless
of the shape of its azimuth pattern.

Look at the loop antennas. The polarization depends from feeding place.
The two masts is like "special" tipped dipole. The masts are 1/2 wave lenght
apart.

1. A full-wave dipole is not self-resonant. Its center-fed impedance in free space is about 2,000 -j600 ohms.

2. None of the equations for the free-space radiation pattern of a full-wave, or any length dipole include terms for its physical orientation.

3. In free space there IS no up, no down and no tilt.

> If you are going to suggest something new it must correlate

Why are you asking the group? ... when you are the one who has been telling
us that conventional EM wave theory is wrong.

You have already been told the correct answer but you chose to rebut it with
a heap of 'longitudinal wave' nonsense.

Well the title of the thread is 'Spherical radiation pattern' and I interpret that as meaning a far-field pattern that is uniform (within the 2 dB margin I offered) in respect of the transverse electric, or transverse magnetic, field strength, or the resulting power-flux density, over a whole sphere.

I'm not sure what you mean by 'total field' in respect of a far-field pattern - all induction components should be insignificant including any 'cross-field' longitudinal ones. Also, my wager is in respect of a hardware antenna being built, not an NEC model.

Regarding your lump of coal and a thermistor - how would you connect the thermistor? Surely that would impose some kind of polarisation however it was done ...?

Untrue. Please read the description linked below, which states that these antennas respond to the magnetic field of an EM wave. Dipoles respond to the electric field.

As the magnetic field of a vertically-polarised wave lies in the horizontal plane, loopstick antennas in AM broadcast receivers are positioned horizontally.

... Oops, scratch that last bit - my mind must have been elsewhere! Of course you'd just drill a hole in it.

Thinking about your lump of coal reminded me about the kinds of antenna used in radiation hazard meters, often three short dipoles mounted mutually perpendicularly, each with some kind of bolometer element at its centre. If one didn't care about polarisation then perhaps a similar arrangement could be used to transmit with a near-isotropic pattern, but that wouldn't be an efficient solution for communication. No, the challenge for Art Unwin, should he wish to put his money where his mouth (keyboard) is, is create and demonstrate a hardware antenna that exhibits a spherical radiation pattern in respect of a single polarisation. That would be useful.

What is the red line in the pattern to which you gave the link?

Chris

> the output impedance?
> --
I think that the OP is not referring to a balun, but instead to an 'un-
un'. This is, in this application, a
9:1 impedance transformer used to 'match' a long(ish) wire to 50 or
75
ohms. A typical use is with an inverted-L antenna, where the feedpoint
is
remote from the house, and coax is used to bring the signal back to
the
shack. The advantage of this arrangement is that the antenna usually
picks
up much less interference from domestic electrical sources. It's
essentially a receive-only device, but can be used for low power
transmit (so I'm told).

The transformer is usually wound with a 3:1 turns ratio, on a ferrite
ring or
rod and, using the correct grade of ferrite and actual number of
turns, it is
possible to obtain a frequency range of 1 to 30MHz (ie the whole of MW
and
SW spectrum).

Of course, the 'matching' is only approximate. It's just that, at
most
frequencies, the insertion of the transformer provides a better match
between the coax and the antenna than you would have if there was
simply
a direct connection. It makes no attempt to be an antenna tuner. For
some
information, may I direct the OP to a recent thread in this newsgroup
(1
August), the subject of which was "UNUN Cores?How To Wind?". The OP
was "Greg <bluehyhena@hotmail.com>".

And then there's Google. There are a few useful links here:

The one who has made the positive assertion is the one who has claimed that by his new theory an antenna can be made that has a spherical radiation pattern. I don't believe in the theory as he has laid out and I don't believe that such an antenna can be built and demonstrated. My wager is in respect of whether or not the protagonist can build and demonstrate such an antenna to back up his own positive assertion.

It is in the nature of a challenge for him to take up if he wishes, and if he does then his bet will be in respect of his positive assertion, but, of course, he hasn't taken it up yet. If he doesn't take up the challenge then nothing new is proved - whichever way you care to interpret that.

This statement is flawed because it makes the assumption what is
sometimes true is always true. The feed point's location may or may
not impact a loop's polarization.

The antenna fits inside a sphere of radius 0.0415 wavelengths.
However, the antenna pattern is not spherical and more closely
resembles the torus produced by a dipole than of an isotropic antenna.
<http://www.cst.com/CMS/images/article105/CPU05_047_600_481.jpg>

An isotropic approximation, which doesn't really qualify for the prize
because the pattern is not polarization and phase insensitive.

Hi Chris,

Others have - the design is not unique to me and has been around for years. I modeled it to merely confirm those reports and that was rather simply accomplished. I have reported these results to interested parties here for the last 10 to 15 years. I am under no illusion that Art has ever used that data as a resource, otherwise it would undercut his claim of novelty.

I've no doubt that other designs meeting your terse requirements could be rummaged up. I have no presumption that NEC fails for this one specific design that is ordinary in every regard to conventional modeling. At a minimum this is only 4 wires. As such, I am satisfied.

Good. Maybe this will encourage Art to have a go at my challenge by
applying his own theories then.

I had seen papers about inverted F antennas before (at an IEE or IET
symposium some ten years ago), and I vaguely recall hearing that some
manufacturers use them in mobile phones, but I'd never seen a pattern as
uniform as the result of your simulation.

art will never accept your challenge. its up to you to prove that his
assertions are incorrect... and then get ignored as he continues to state
the same things in many different forms. unless you can capture one of his
diamagnetic levitating solar neutrinos and show that it doesn't sit on the
antenna element and jump off when a pulse of current hits it you will never

be believed... and even if you did capture one he would tell you it changed in flight from the sun.

Hi Chris,

For a more academic treatment, the antenna is also known as the
"U-Shaped Antenna of Shtrikman." His has three wires, my fourth wire
is much like the J-Pole feed point attachment.

Now, one proviso: this is not an isotropic in the sense of providing
equal polarization at any angle. Nothing can accomplish that due to
that requirement being impossible to meet (the so-called "hairy ball"
problem). So, I simply resolved that with my carbon golf ball with
its thermistor for detecting the Inverted F's total field to within
the degree of less than 2dB variation over the shell surrounding the
antenna.

>Good. Maybe this will encourage Art to have a go at my challenge by
>applying his own theories then.

As I've shown, they are not his theories. Art doesn't have theories,
they are illusions. Shtrikman's antenna has a model and a practical,
real example that agree with one another in performance. The design
is revealed and can be reproduced by anyone. No advanced math is
demanded to perfect the results. No allusion to nuclear forces is
required to explain any principle. Anyone can, and HAS built an
antenna that Art can only mumble about. Perhaps I am mislead about
this mumble, having kill-filed him, as I see his contribution (sic)
only through other's quotes; few of which are full quotes (I can
understand why).

This last week in my driving through rain city, I've seen a street
corner beggar who has worked one particular intersection for a couple
of years now. He has a weather protected laminated board describing
his plea, and he wears goretex weather gear that I couldn't afford. He
does have this hang-dog appearance and shambling shuffle tho'. What is
one to believe when it comes to claims? Clearly money talks. Who
knows? He may have a patented system and sells franchises.

Kris,

The best protection against rust it something usually found near the shipping dock...lithium grease. The dipole looks strong. I have eliminated coils in all but my 40 meter beam and there I use high grade electrical black tape as do several manufacturers here in the USA.

I would be interested to find how the dipole works on 40 as its quite short there electrically and probably very narrow banded. I have a friend with the MFJ-1785 big brother and his works great on 40 but so far its down 2 S units to a normal Dipole on 80.

I had understood it to be impossible on the basis of normal physics but Art
Unwin's claim wasn't clear in respect of polarisation.

Now I understand what you meant by 'total field' - sum of powers of
components in all polarisations.

Hi Chris,

Black body radiators do qualify as Isotropic; and as Art has claimed
high efficiencies for RF impracticalities, it must be for efficient
Infrared emission.

Too bad it doesn't have the 756 spectrum scope.
And there is no mention of the 706's SWR plot.

A me-too Kenwood ts-2000 when it should have been a
proper superset of the 706/7000 and 756. Yawn.

... but are randomly polarised, and I'd expect communication between a randomly-polarised antenna and either a normal, polarised antenna or another randomly polarised one to be lossy in comparison with the unusual case.

Nevertheless, the principle that heaters are highly efficient is an amusing, occasionally useful one - standby dissipation contributing to heating your house and all that.

You appear to have changed your identity from S* to A* !

The answers according to the physics that real-life radio communication depends upon, and was designed by, are:

A single EM wave is plane polarised. It is composed of a magnetic field H that acts in a direction perpendicular to the direction of propagation, the magnitude and sign of this field varying as a travelling wave in the direction of propagation, and an attendant electric field E that also acts in a direction perpendicular to the direction of propagation. The magnitude and sign of the electric field varies as a travelling wave, coherent and in phase with the magnetic field and the magnetic field is a direct consequence of current flowing in the transmitting antenna. The directions in which the H and E fields act, in the plane transverse to the direction of propagation, are mutually perpendicular and the direction in which the E field acts, by convention, defines the polarisation.

Thus a single EM wave has a single, plane, polarisation. Different combinations of waves are possible such as circular polarisation and, more generally, elliptical polarisation, but these can always be resolved into orthogonal plane components.

Simple antennas like straight-wire dipoles and loops transmit and respond to plane polarised EM waves. More complicated antennas can be made to transmit and receive circular polarisation of one sense or the other, and generally an antenna will tend to transmit or be sensitive to some combination of different plane polarisations. In addition to radiated EM waves, there are also induction fields in a region close to the antenna.

In a system that contains no anisotropic material (e.g. magnetised ferrite), when the distance between transmitting and receiving antennas is at least tens of wavelengths, the principle of reciprocity applies. By this

principle the properties of an antenna when transmitting are the same as when it is receiving - the properties including the polarisation, radiation pattern and terminal impedance.

If you find any of this interesting, please don't believe what I've written here but go to a technical library (e.g. at a University) and look up the authoritative sources - books on antennas and propagation by Kraus, Jasik, Jordan and Balmain, Terman, etc.

Please _do not_ respond here telling me or the group that EM waves are longitudinal and are not polarised.

... but the libraries are probably closed today so, for an instant, online source you could do worse than visit http://www.globalsecurity.org/military/library/policy/navy/nrtc/, download the NEETS module 'ELECTRONICS TECHNICIAN, VOLUME 07--ANTENNAS AND WAVE PROPAGATION ' and read it. It's based on the same, real world physics.

It's been a long time, but I think the non-b version was criticized
for having a lot of RF on the feedline. That would distort the
radiation pattern somewhat. The b version corrected that.

Uh, Breaker One-Nine, this here's the owned N8
You got a copy on me Lelnad Scott? C'mon

Uh, yeah 10-4 N8, fer sure, fer sure
By golly it's clean clear to Fag-Town, C'mon

Uh, yeah, that's a big 10-4 Lelnad,
Yeah, we definitely got us the front door good buddy,
Mercy sakes alive, looks like we got us a convoy

Was the dark of the moon, on the sixth of June
and Doug was getting it on with hogs
Blowing Cabover Pete with a reefer on
And having sex with stray dogs
We was headin' fer bear on I-One-Oh
'Bout a mile outta Shaky-Town
I sez Lelnad, this here's the N8
And I'm about to put the hammer down

Cause we gotta little ol' convoy, rockin' through the night
Yeah we gotta little ol' convoy, ain't she a beautiful sight?
Come on an' join our convoy, ain't nothin' gonna git in our way
We're gonna roll this gay ass' convoy, cross the USA
Convoy... Convoy...

Uh, breaker Lelnad, this here's N8
Uh, you wanna back off them hogs
10-4, about five mile or so, 10-roger
Them hogs is gittin' in-tense up here

By the time we got into Tulsa-Town
We had eighty-five trucks in all
Pink ones up on the clover leaf
And I wanted to lick Mopar's balls

Yeah that sounded as good as bugs on a bumper
I even thought of Dave Hall losing his hair
I sez callin' all trucks, this here's N8
I really want to see you all bare

Cause we gotta great big convoy, rockin' through the night
Yeah we gotta great big convoy, ain't she a beautiful sight?
Come on an' join our convoy, ain't nothin' gonna git in our way
We're gonna roll this gay ass convoy, cross the USA
Convoy... Convoy...

Uh, you wanna give me a 10-9 on that Lelnad?
Uh, negatory Lelnad, yer still too close
Yeah, them hogs is startin' to seal up our anuses
Mercy sakes, you better back off another ten

Well we rolled up Interstate 44
Like a rocket sled on rails
I though of Twistedhed's radio
and how it almost landed me in jail

By the time we hit that Chi-Town
I was thinking about Tim Nebo's ass
and all the times he keyed on me
while chewing the rag with Brass

Don't forget Jay and Pain and Ice Cold, too
and Jim Hampton way up north
Yea them CBers do something to me
make me question my self worth

Well we hid like kids and squealed like girls
and pranced around in women's clothes
those bad men in rec.radio.cb
make us realize we're dirty ho's

Hey Landshark, listen
You wanna listen up for my weak radio?
Yeah, I just wanna be heard man
I needs all the help I can git

Well we laid a strip fer a Jersey man whore
Prepared to play with his behind

I was having nightmares about sideband mode
and freaking out over freeband time

I sez Lelnad, this here's the convicted N8
we just ain't a never gonna learn

So I clutched the mic
as I cried all through the night
I said I hope rec.radio burns

Cause we gotta gay ass convoy, rockin' through the night
Yeah we gotta gay ass convoy, ain't she a beautiful sight?
Come on an' join our convoy, ain't nothin' gonna git in our way
We're gonna roll this gay ass convoy, cross the USA
Convoy... Convoy...

Uh, 10-4 Lelnad, what's yer 20?
San Francisco?!
Well you oughta know what to do with them dogs out there fer sure
Well mercy sakes alive good butty
We gonna back on outta here
So keep the feds off yer ass

And the magistrate off yer... tail
We gonna catch ya on the flip-flop
This here's N8 on the side
We gone
Bye, Bye...

A much simpler, and compelling explanation:
what you see is what you get.

If it looks vertical, the polarization is vertical;
If it looks horizontal, the polarization is horizontal.

It thus stands to reason that if the radiator is U shaped you see both
horizontal and vertical - hence the full sphere filled with radiation.

This closes the simple answer, which of course drives a very lengthy
explanation - there is no such thing as a free lunch:

Now, I can well anticipate some wag pointing out that they are
standing, looking at these "goal posts" edge on and see only the
vertical supports. "There is no horizontal view - no horizontal
polarization. It can't be isotropic!"

Of course it can't; and yet the vertical radiation fills the null of
the horizontal (and likewise, the horizontal fills the null of the
vertical). Total field is spherical.

What does this make of a tilted radiator? What you see is what you
get. At some perspectives it looks goofy horizontal AND it looks
goofy vertical. In other perspectives it just looks vertical. As Art
might protest: "Never mind goofy, how much horizontal?" If we reduce
this to a number of goofiness, a trig function would serve quite well.
Most students who were trained in mechanics would recognize the method
to deconstruct an angle into its two, XY, components. If the tilt
were 45 degrees, in full view of that angle you must experience the
single antenna as having two equal vertical and horizontal
contributions to radiation. If it were tilted 30 degrees, obviously
one polarization would dominate over the other. Ground would compound
the issue, but would not negate the general principle.

This last part returns us to the discussion of isotropism which encompasses the topic of Lambert's Law which is generally confined to a black body radiator (or the sun from a great distance as it fails to be isotropic in the near view, such as we have here on earth). Few here need concern themselves with this unless they are making patch antennas. However, within the discussion above, the topic of view, angle, and radiation contribution are wrapped up in Lambert and cosine.

But there is the second direct consequence. If the current oscilate at the
ends is developed the very high voltage. The high voltage produce the
electric field. So you can wrote: "the electric field is a direct
consequence of voltage developed in the ends of the transmitting antenna".
This electric field generate the magnetic field and so on. So the Hertz'
dipole has the three sources of waves. The centre and the two ends.
It seams that waves from the centre are mainly transverse and that from the
ends mainly longitudinal.
Long wire antennas have many sources. Directional patern is number source
dependent.

You do not like the word voltage. May be the better is polarity.

R. Clark wrote: "Actually you have mixed up two different characteristics.
Polarity
and polarization are NOT the same thing. With RF radiation, the wave
is constantly changing polarity (that is why the source of RF is
called alternating current), but within the "line of sight" of the
antenna, the polarization for a dipole is defined by its angle to the
earth as viewed by the observer.

If you see an horizontal dipole, it produces alternating polarities of
waves with horizontal polarization. If you see a vertical dipole, it
produces alternating polarities of waves with vertical polarization."

EM waves by Heaviside are transverse. Now we should check if he was right.

You have confused the telegrapher's equations with propagation.

Before you recite an authority, you really need to understand them.

>the arx2b and the original arx2?

My understanding is that the lower section (with its radial stubs)
serves as a decoupling element, and greatly reduces the possibility of
RF current flow on the lower mast.

The original ARX2 seems to have a reputation for being somewhat
installation-sensitive. In some installations, enough RF can flow on
the mast and/or feedline to alter the antenna's radiation pattern...
the main lobe can "squint" away from the horizon and thus reduce the
useful gain of the antenna somewhat. In other installations (with
different mast and feedline lengths) this wasn't as much of a problem.

Adding the decoupling section to the design has (from what I've heard)
significantly reduced the problem, and allows the ARX2B to perform
more consistently than the ARX2 did.

Standard copper-pipe J-pole antennas (and similar designs) tend to
have the same issue - unless you decouple them from the mast and
feedline somehow (e.g. insulated mount, and a choke on the feedline)
their pattern can be installation-sensitive due to RF current flowing
where you don't want it.

There is no extra mast. You are using the support mast
below the feed point. The extra parts are a 50 inch length
of coax, and a union to support a set of 20 inch long radials.
The radials are connected to the shield of the coax.
Years ago I converted an original Ringo Ranger to a
Ringo Ranger two using home brew parts.
I then did comparison tests with and without the radial
set. Made a huge difference in performance in my case.
Cushcraft seemed to consider it a third 5/8 WL element,
but I tend to consider it a decoupling section much
like the lower cone you see on an Isopole, or using
a 2nd set of radials or cones below a ground plane.
Yes, it is worth converting. The ARX2B is a pretty good
antenna. Not quite as good as the Isopole, but close.

I have seen people swear by and swear at Ringo Rangers. Is this
because of by chance some people get the right/wrong length mast and/
or coax length?

Art wrote:
"Thus if we have a radiator of one WL that is tipped in space and near zero resistance in impedance metric we will then attain a spherical radiation pattern with Poynting`s vector and thus a demonsration of point radiation together with further evidence that radiation is of particle and not of waves."

No matter how Art`s words were combined, I don`t see in them any such evidence. Even Art agrees that Maxwell`s equations correctly produce answers to where the energy goes.

The 1955 edition of Terman`s "Electronic and Radio Engineering" shows the radiation pattern of one WL of wire in Fig. 23-4 (b) on page 867. It consists of four lobes each making an angle of 54 degrees with the axis of the wire. The pattern deviates from a spherical pattern by a lot. So much for "equilibrium"!

Cecil pointed out that in physics, electromagnetic radiation is treated with duality, using either particle theory or waves, whichever is more convenient for the problem at hand.

Maxwell solved the problems of radiation using wave equations which are said to be four of the most influential equations in science.

On page 864 of Terman`s 1955 opus he writes:
"The laws governing such radiation are obtained by using Maxwell`s equations to express the fields associated with the wire; when this is done there is found to be a component, termed the radiated field, having a strength that varies inversely with distance.

If Art would just absorb Terman`s chapter on "Antennas" I doubt he would write such nonsense.

Best regards, Richard Harrison, KB5WZI

It is commonly known: "Heaviside said that mathematics was an experimental
science. He organised Maxwell's mathematical work into the four equations
which we now call "Maxwell's Equations".

Maxwell made the model of solid ether. The four equations by Heaviside is
rather "fluid analogy".

"Now Heaviside had the concept of the TEM Wave, which Kelvin and Preece did
not. With these two formulae, he could give a gloss of mathematical style to
his assertion that, properly treated, a slab of energy current could
propagate at the speed of light without distortion. This assertion had
massive practical implications, but Heaviside was obstructed for decades."

Only the change in current and charge, over time, produces EM
radiation. That radiation includes both the magnetic and electric
fields, at right angles to each other and to the direction of travel.

In the case of a self-resonant, center-fed, 1/4-wave dipole, current
is maximum at the feedpoint and minimum at the ends of the dipole.
Therefore the ends radiate very little of the total applied power.

Below is what John Kraus writes about this in Antennas, 3rd edition,
page 12:

QUOTE
A radio antenna may be defined as the structure associated with the
region of transition between a guided wave and a free-space wave, or
vice-versa. Antennas convert electrons to photons, or vice-versa.

Regardless of antenna type, all involve the same basic principle that
radiation is produced by accelerated (or decelerated) charge. The
basic equation of radiation may be expressed simply as:

IL = Qv (A m s^-1)

where

I = time-changing current, A s^-1
L = length of current element, m
Q = charge, C
v = time change of velocity which equals the acceleration of the
charge, m s^-2

Thus, time-changing current radiates and accelerated charge radiates.

END QUOTE

Correcting myself, that dipole would need to be about 1/2-wave long
for first self-resonance. But neither form of this dipole radiates
very much from its ends.

That could be the case with the non decoupled version. :/
But the RR2 is a pretty good antenna. I used one for a long
time and never had any problems.
The mast and coax length could be fairly critical on the
non decoupled version.

Like I said, I converted an old ARX2 to a ARX2B and then
compared the two when receiving local signals.
The difference in my particular case was quite large.
I'm talking 2-3+ S units on the radio meter which
actually would be a huge difference. It was quite
apparent that the common mode currents were really
whacking the pattern on the one I tried without the
decoupling section. I assume most was from the feed line.

Richard cannot read this. However I find his posting to be rewarding .
The present aproach to radiation is that a free electron is torn away
from the nucleous of an atom which creates uncertaincy. Such an action
is that of the strong force which is akin the the splitting of an atom
where such an action would release electrons such that they would
bombard electrical networks such as in Hawaii. When one uses Maxwells
equations
it becomes very obvious that with decreasing impeadance radiation
increases until we get to the point of zero impedance where reality is
forced to be reviewed.
Since we now recognize that radiation is not created by the radiator
itself as it is only a carrier of a radiator, the model used must be
of cylinder type of homogeonos free electrons
where removal of the free electrons/particles is by a "weak force" and
not a strong force.
Thus in reality the model to be used is that of a cylinder where the
"stiction" of each electron,(I should really keep to the term particle
so one does not automatically insert neutrinos or a subset of
leptons) to a diamagnetic material is effectively replaced by a hoop
stress which first showed up in the boundary of the "Big Bang".
Now we have something that meets reality, where increase in current
applied creates an increase in radiation and where the model is seen
to be a boundary consisting of particles bound to each other! This is
basically implied by Maxwell's equations as illustrated by the
computer programs where radiation increase is proportional to the
decrease of impedance
of the energy robbing metallic radiator and where cylindrical boundary
model increases it's share of the current applied for continued
radiation and still is in concert with known laws
without resorting to extreme low temperature to attain "zero
impedance" which lacks reality.
As a side note. It is the arbitrary boundary in shear (spin) which
provides the Weak Force of the Standard Model as foreseen by Einstein
when he took on his fruitless search. And it would appear that the
reversal of the positive sign of the shown "Radio World" material is

somewhat supporting of this posting but that should be the subject of
a separate thread.

If radiation occurs at the end of a dipole (which it does) it exists
only in the near field
because of its lack of spin. ie charge dissipation but without spin.

Decreasing the feedpoint impedance of an antenna to 0 +j0 ohms (if
that were possible) does not maximize radiation.

The first term in the antenna impedance specification in a practical
antenna consists mainly of radiation resistance -- which is required
in order for radiation to occur. Radiation resistance is a function
of the electrical length, diameter and form of the radiator exposed to
space. If it is zero then there is no radiation.

Higher radiation resistances lead to higher efficiencies for the
antenna SYSTEM, because then the power radiated can be much greater
than what is dissipated in the relatively smaller I^2R losses of the
system.

Side note, Roy. I take a lot of Morotcycle rides to the north central part of PA, and being a remote area, that have a fair number of radio systems to tell them of the shape of the power lines in eh area.

They use a ground plane antenna that consists of a spring mounted vertical, and two horizontal radials. They are pretty homely.

>particle and not of waves."

Hi Richard,

Lot of contradiction in the short space of one sentence, isn't there?

Tipped in space? Who but an astronaut know this? Is an antenna tipped if he wasn't there? (The logical knot formerly known as "If a tree falls in the forest, does it make waves or particles?")

A vector creates a sphere? A vector with no tail, and all head? Must be a new science of mechanics there. If there is any lesson to be learned from the past, then Newton has been discarded for heresy.

Where "radiation is ... not of waves" invalidates every patent description Art has ever submitted - fortunately that doesn't have any impact on the legality of their issue.

Let's see, where one of Art's patents teaches that reflectors are shorter than the driven element, and the directors are longer, was this due to the newly revealed particle theory? Art has steadfastly refused to explain this novel design feature until - well certainly not now (or ever?) and I will never see his mea culpa. Such an admission would plunge the postings count into oblivion without that full quota of nonsense.

What happened to his other patent's teaching of "length efficiency?" Now that we have witnessed the dawn of the tilted equilibrated full wave radiator (TEFWR), it would seem that "length efficiency" (which formerly compressed the antenna by snipping off the ends that didn't radiate) has been sent to the neighborhood Re-education Kamp.

As I stand on the corner waving goodbye to that bus, I fondly recall how the logic stood that no current could be found on the tips of radiators, thus trim them off to no loss of radiation. It took very few decades before Art had then recognized that his new antenna's tips had no more current than the full-length one, and he trimmed that one once again! New and improved (as the saying goes). Another decade passed into the new millennium and he observed that he could extend

this logic once again to the point where his last design encompassed a 160M full sized antenna in the space of two shoe boxes. The TRIUMPH OF TITANIC PROPORTIONS.

Yes, I realize the irony in caps and terms chosen to illustrate this, the Ritual Art of Antenna Bris. The careful reader may wish to count the number of accumulated ironies, retorts, confutations, and quips; and submit them on a sheet of paper inclosed with $2 in postage stamps inside an envelope (send no coins), posted to me. Those who can show the correlation between each and the appropriate patent number will be awarded Mauve bonus points. Winners will be announced at a future date. [Offer void where permitted by law.]

>Cecil pointed out that in physics, electromagnetic radiation is treated
>with duality, using either particle theory or waves, whichever is more
>convenient for the problem at hand.

Well, there's the match for this pair of bookends. Cecil could have as easily contributed with an inventory of his left pocket's contents.

2006. Did I make a mistake in connecting radials to...

Newsgroup: rec.radio.amateur.antenna
Date: 2009-09-14 18:32:35 UTC
From: mcalhoun@sdf.lNoOnSePsAtMar.org
Message-ID: <h8m283$m77$1@chessie.cirr.com>
Source record: 13118

I've read a lot about radials: elevated vs. gull-wings vs. underground, how many (120/64/31/16/4/2/0), etc. After reading the following, maybe someone will tell me if I did right or wrong. This is long, but the nitty-gritty details might be necessary for a good answer.

I recently erected a 20-meter vertical in my front yard with 16 equally-spaced, about-20-foot-long, UNinsulated radials (electric-fence wire) around its base starting at a metal plate and just laid on grass about 3 inches above the soil and "pinned" (with about 8-inch-long stiff-wire loops) to the soil at the ends to keep them taut/straight. The metal plate was "grounded" with a 2-feet-long metal rod driven into the soil.

The antenna worked acceptably well, so I decided to make it more permanent (and the radials less-likely to be tripped over!-) by mowing the grass REALLY short and resituating the radials such that they are now only about an inch above the soil (and will soon be hidden below 2 inches of grass). I also "pinned" the radials a little more tightly to the soil once or twice along their lengths.

While doing that, I realized that if I lengthened two of the radials by about 10 feet, I could connect them to 8-foot ground rods (at the bases of a tower and a flagpole) that were themselves connected (with thick, multi-strand, insulated copper wires that run from the tops of the ground rods horizontally about 10 feet and then 9 feet down) to a 75-foot-long Ufer ground that goes around about half of the foundation of my basement.

My worry revolves around the fact that, while my radials are NOT *IN* the soil, they are pretty-well connected TO the soil, and two of them are connected to the best ground I could buy when my house was being built. Have I done wrong by grounding them, or should I have used INSULATED radials and NOT "pinned" them to the soil and NOT connected them to my Ufer ground?

Hi Myron,

What you describe up to this "worry" sounded fine to the point of
being classic.

The radials are in very tight coupling with "ground" (earth, common,
...). As for the rest of it, the Ufer ground, the rods, and extra
accoutrements - they reduce shock and lightning hazard and are only
vaguely related to your RF needs.

As always, ensure that all grounds (including the point where all the
radials converge) are tied together according to code.

Parts with r-f-current flow, the greatest radiation occurring from locations along the radiator where current is greatest.

Current flow is near zero at the ends of any unloaded dipole, and at the top of any unloaded vertical monopole (even those in directional arrays).

Didn't spot the explanation (have done now, thanks) and I did wonder if the issue was that he couldn't type his own initial correctly. For a moment I wondered if there were two alter egos: A* asks a question, apparently sincerely, then, when given the answer, S* responds with rebuttal of the correct answer and a lecture based on paraphysics and historical dead ends. However, that would be bonkers.

I might add that this solves a nagging problem of mine. What is
normally referred to
as a "half wave" is in reality the equivalent of a "full wave folded
dipole" where the particle sleeve represents the other half of a wave
length (see "U" antenna mentioned by Richard)
Of course the inner element formally seen as a radiator takes on its
true form of a carrier only but does provide for the required
equilibrium even tho the lumped load capacitance area in between "has
disappeared" or the equivalent of cancellation of lumped loads to
provide maximum efficiency while accounting for all forces involved.
This now completely solves the radiation problem, that has lasted a
Century, in compliance with all existing laws. as well as being
suplimented by the Gaussian extention . The above also solves the
identification of the Weak Force which provided completion of the
Standard Model as envisioned by Einstein. All is now of a proven
nature UNTIL my peers can point to where it deviates from existing
laws of Classical Physics.
It has been fun over the years exposing the self perceived psuedo
experts of this newsgroup as well as exposing to the World those who
follow and quote only books in the effort to resist change.
Bottom line is.
If you can't develop a theme from first principles you are just a
follower
and not a true Engineer.

Well, movement of electrons is the basis for current flow. 'Torn away' is an interesting choice of words, but separation of electrons from an atom is commonplace. (BTW the electrons come from the atom, not the nucleus.)

>> Such an action
>> is that of the strong force which is akin the the splitting of an atom

Removing an election and 'splitting of an atom' are vastly different concepts. You are talking about two vastly different things.

So, explain this model. A cylinder of homogeneous (whatever that means) free electrons would repel each other and dissipate into space. They would be lost forever.

>> Thus in reality the model to be used is that of a cylinder where the

What is the hoop stress. You have created another undefined term which is
meaningless.

You seem to have created your own, new, definition of a folded dipole. One
where the length in wavelengths is no longer the distance from end to end,
rather the length of material used (or the perceived circuit path).

What is more amazing is that your definition of full wavelength is now 1/2
what you originally thought it to be. Yet that apparently doesn't cause you
significant concern.

> Of course the inner element formally seen as a radiator takes on its
> true form of a carrier only but does provide for the required

However, you completely ignore the 'laws' regarding the fields that are
generated by the current in the 'carrier'. Or that they would cancel the
result from the field generated by the outer element.

> This now completely solves the radiation problem, that has lasted a
> Century, in compliance with all existing laws.

You have not shown, in any way, how this is in compliance with what you call laws. Since you show no math, nobody can really know what you are talking about.

> as well as being
> suplimented by the Gaussian extention . The above also solves the
> identification of the Weak Force which provided completion of the

> nature UNTIL my peers can point to where it deviates from existing
> laws of Classical Physics.

Proof of your concept is something YOU PROVIDE. Nothing is proven until you can show, in a clear manner, what you think you understand about how antennas work. If you really have some new idea, you should be able to document it and verify it with real work experiments. Your work should also be verifiable and able to be repeated independently by others. When that happens you may have developed some new scientific understanding.

> It has been fun over the years exposing the self perceived psuedo
> experts of this newsgroup as well as exposing to the World those who
> follow and quote only books in the effort to resist change.

I would venture to guess that it is not the others resisting change, rather it is their opposition to someone who proposes concepts that ignore and contradict the current understanding of antennas. If you have some new idea regarding antennas, it should not conflict with the understood state of the art, rather, it should expand the state of the art. Your ideas conflict in numerous areas which other have pointed out. However, you choose to ignore those inputs.

> Bottom line is.
> If you can't develop a theme from first principles you are just a
> follower
> and not a true Engineer.

An engineer does not need to develop all his ideas from first principles. Rather, existing ideas are extended. The engineer should know the first principles, but deriving everything from first principles is grossly inefficient.

But the big thing is you just spout those first principles without really understanding them. The true engineer knows what he is talking about.

The true engineer also validates his work with models and prototypes. He tests his ideas to show they actually work as expected. You play with models (but never adequately share them) and your prototypes have not been shown to have real usefulness as an antenna.

When asked to provide results from experiments any good engineer will have, or get, data that supports his position. When you are asked, your favorite answer is 'I don't work for you'.

You even use this response when someone gives you a suggestion on how to verify the cause of a problem you are having.

You are NOT an engineer. You are NOT a scientist. You may have been an engineer in the past, but today, you are not showing that ability.

The pity is, you believe what you are doing. That is the only thing that can be verified. (Verification comes from the fact you did submit a patent application. That is the only thing that can be independently verified.)

And someone has pointed out something is wrong. As is typical, you avoid the point and ignore the conflict with your position.

> You were the first to state I was in error by applying a time varying
> field to Gauss's law of Statics and the group followed your position
> where no body provided academic proof.

You provided no proof of you assertion.

> Then Dr Davis came along and provided academic proof per its
> legitimacy. Having a Doctorate from MIT and working for the Space
> Agency gives him some what of a track record.

All Dr. Davis stated was the relationship between Gauss and Maxwell. You claimed to come up with something new, and it was there all the time. He did not say anything about the validity of your ideas regarding antennas.

> I then found out that

> then continue the discussion.

If you extension to Gauss is just a re-iteration of Maxwell, then you have presented nothing new.

Time and time again you have shown that you are not willing to discuss. You do a lot of verbal handwaving, but there is no substance.

I submit that industry-recognized, expert sources on the subject of antennas such as Kraus, Balanis, Johnson/Jasik, George Brown etc were and are much more likely to understand and respect those first principles.

Anyone can develop and publicize a theme about the operation of antennas.

Scientifically PROVING that such a theme is correct takes a true "Engineer."

Yes that is normally true but how many people at the table has asked
for the salt
when it was right in frony of them?

>
> Anyone can develop and publicize a theme about the operation of
> antennas.

I consider that a difficult task without running into trouble with
existing laws.

>
> Scientifically PROVING that such a theme is correct takes a true
> "Engineer."

When you deliver a theme or paper in front of college graduates,
professionals and
above, one assumes that they are fully aware of the basic laws
involved. Since your only connection to antenna engineering is the
repetitive pushing the "on" and "off" button at a local radio station
as its resident engineer it is more than possible that you have not
had a academic training. Your past posts gives some truth to that
statement, tho it is possible that I will have to stand corrected if,
as with many, age has taken its toll.
As you have stated in the past
. "your move"!
Point to a law that I have violated of which you learned about in
academia. Alternatively
ask the question from your local academic centre where interllectuals
reside who have more knowledge of such things than either of us will
ever attain.
As for me I am at peace with my offering and thus can move on until a
violation of law is
presented.

you violate the range of the weak and strong forces. they are both confined
to the nucleus of the atom and have nothing to do with the conduction band
electrons.

what is the easiest/cheapest way to add the decoupling?
Just add some 1/4 wavelength radials 1/2 wavelength below
the arx2?

And why not? You keep shooting from the hip on baseless statements.
For me I have supplied a trail for examination that I believe is in
complience of existing laws.
You were the first to state I was in error by applying a time varying
field to Gauss's law of Statics and the group followed your position
where no body provided academic proof.
Then Dr Davis came along and provided academic proof per its
legitimacy. Having a Doctorate from MIT and working for the Space
Agency gives him some what of a track record. I then found out that
one of the prolific antagonistic posters did not survive high school.
True, he was suspended, so it was not really his fault!
Obviously such things are not the norm in this group but it does give
you thought regarding a antagonistic track record when lacking in
independent thought shoots from the hip or extract a paragraph from a
book like a copy provided by a copying machine of which he has no
understanding.
Nope, I have provided details of my independent work all of which
follows the existing laws
of Classical physics. At this time I see it as a worthwhile theory
with merit and possibly more if there is no violation of existing
laws. If you have doubts then contact your alma
to provide consistency in your allegations. Or alternatively wait for
the PTO printing of my
present concluding patent request such that all details are available
for inspection.
This newsgroup is available for free speech but for the reader caution
is advised. Reverse your position on the Gaussian extension so we can
then continue the discussion.

Ah!

But if you extrapolate the nucleus as the sun of the solar system, the
earth as an electron; then the conduction band is easily managed with
a weak force as significant as a bite of bread stuck to the roof of
your mouth with peanut butter.

Peanut butter is diamagnetic, and if you buy the crunchy style, you
get the combination of waves and particles.

[this premonitory peanutbutter presentation posting possibly protected
by provisional patent pending]

Art,

How do you respond to my comments to your statements above, seeing as
though you have responded to later r.r.a.a. posts with no further
response to the above sequence?

NO RESPONSE from you easily may be taken to understand that you cannot
defend/support your position on such subjects.

If your lack of response was an oversight, then probably most of us
will understand.

But what IS your position on this subject?

RF

So Art again fails to step up when asked to prove something.

"I'M RIGHT!!! PROVE ME WRONG!!!" is Art's continual wail. No Art, you have to prove you are right, and just claiming it isn't even a start.

FRAUD == ART

You used David as your role model! You also stamped all over Dr Davis.
You would be better off standing on David's shoulders and staying in
lock step with him and hold that silly tongue of yours for your next
partner.

I don't know who you are or where you came from into this discussion
that has lasted for years. I did read a portion of what you stated but
you must recognize that this newsgroup
is like a magnet to those who want to sound off without revealing
themselves. It is called free speechand I know not where you fit in! I
am sorry I inadvertently came into your court room your honour. Joe
the judge I presume and not Joe the plumber
That is the best I can do for you until the patent office prints the
rest.
Then you can base all the above accusations that you made prior to the
facts

Years is a fallacy. You showed up with your fantasies quite recently,
not even 2 years ago, at least with the nonsense you currently spout.
If it's true, prove it.

You have gotten farther and farther from reality as time has passed. If
it's true, prove it.

You refuse to give proof for your claims. If it's true, prove it.

You refuse to refute proofs against your claims. If it's true, prove it.

You won't give us a design to test because you know none of them
actually work the way you claim. If it's true, prove it.

Your claims of diamagnetic levitating neutrinos and other nonsense has
nothing to do with reality. If it's true, prove it.

You are a FRAUD. Prove you are not.

And I will predict your answer, if you give one, will be equivalent to
"You need to prove I'm wrong".

No. "Success" is showing up the self perceived experts.
The question is why is adding a time varying field to the Gaussian law
of statics illegal ?
Or stated another way, what is it illegal by changing a static field
into a dynamic field?
This is not trolling. I am exposing people for what they are and they
are fraustrated
in their inability to show me as wrong or even having a book that
states where and why I am wrong. This is not rambling. Since when is
the truth rambling? If you are an expert take up the challenge in
terms of academics or consult a professor for an answer Either is
acceptable for the purposes of debate of what is true or not
true.Everything I have stated
stands upon this very point So guys, direct yourselves at the root
instead of floundering around in a aimless fashion.
And as far as the size of the audience the bigger the better the
exposure and the more success I have against those who rely on

slander. I want this to be as wide spread as possible instead of
running away. Live with it . I am quite sure that many hams around the
World is following this augument looking for that first person you
will take up the challenge
and provide closure with an answer to this very simple question,
without the fear of recrimination from the group all of which say it
is illegal. Until then......

The factory version uses some kind of donut thing with
threaded holes for the radials. In my case, I just rigged
up a L plate of sorts that I drilled a hole for a coax union.
I used stiff wire radials that I bent into a short L at the end
and clamped them to the mast at that same plate.
The plate and radials naturally are grounded to the support
mast. You run a 50 inch length of coax from the feed point
down to the union on the radial/union plate. Adjust the
clamp so it's fairly taut. The radials are 20 inches long.
Not much to it. The trickiest part is making a union plate
and clamping it to the mast. Just use your imagination.
Not really critical as long as it's stays in place and grounds
to the mast. You can buy the threaded coax unions at
most of the radio parts stores. Maybe even rat shack.

Your problem is not understanding the motion of charges in the antenna.

Sure, the derivative of a sine wave is 0 at the peak, but this does
not directly translate to the motion of the electrons
at specific locations in the antenna.

Look at the antenna current as an electron oscillating
back and forth between the ends. The position over time is described
by a function. Throughout the entire length, the electron is
changing velocity (accelerating).

Hint: the _voltage_ at the feed point may be described by a sine wave.
Your challenge is to determine how the electrons move in response
to that sine wave.

Part of understanding this is knowing the difference between what is
happing as time progresses at the different parts of the antenna.

The trick to understanding this is to carefully do and understand
the mathematics that are involved.

Hi Tom,

Actually Art arrived back in the dark ages of the fin-de-siecle. He had just had a patent issued for a new invented antenna and asked if anyone could explain how it worked. (drum-roll)

Several were astonished (as I have already mentioned) to find that his antenna design had reflector (the new and improved model had two) elements that were shorter than the driven element, and the director elements longer.

Well, when no one could fulfill that request, we've been sub-morons ever since. It's a rare honour that he keeps coming back here for the validation of cretins when the Nobel Committee is located in Sweden.

At oscillations the current start from zero, accelerate to max speed and
deccelerate to zero.
At the max speed no acceleration at all.

No, you have it wrong again - the current must be zero at the ends, there is nowhere for it to go, and there cannot be acceleration of charge is there's no current. Please go away and read some books and the NEETS module to which I provided the link.

Tesla created HF transformers. He didn't design them as antennas but, because of their significant length at the operating wavelength, they did act that way to some extent. The metallic ball (often a torus nowadays) is a means of terminating the secondary in a way that reduces spurious discharges - its radius of curvature is large. His ideas to distribute electrical power using Tesla coils were crazy and dangerous, but some argue he was the inspiration for AC distribution at much lower voltages, which is a good thing.

There is very little apparent similarity between Nicola Tesla and that 'Art Unwin' character. Tesla was an inventor who realised amazing feats of hardware construction, some of which worked as intended. 'Professor Unwin' doesn't appear to create anything in hardware - he just talks about his own, paraphysical theories and expects others to believe what he says.

Again, don't believe what I write - go to a technical library and read the stuff that made it into books. You can't rely on what people write on the

internet; there are too many 'Unwins' out there.

At HF frequencies, the electrons move hardly at all, tending
to oscillate back and forth in place. The idea that electrons
race from end to end in an antenna is simply false.

http://c2.com/cgi/wiki?SpeedOfElectrons

"... for a copper wire of radius 1 mm carrying a steady
current of 10 Amps, the drift velocity is only about
0.024 cm/sec!"

For a 100w 10 MHz RF wave, you can divide that distance by
more than 10,000,000. Exactly how far can the electron travel
in 0.05 microsecond?

It is the photons emitted by the electrons that travel at
the speed of light in the medium. That's the fields surrounding
the antenna conductor, not the electrons in the conductor.

Hi Chris
The question that goes to nub of Arts claim is
why is adding a time varying field to the Gaussian law of statics
illegal? or to state it another way,
How is it illegal to change a static field into a dynamic field?
can you, will you answer the question or are you just sitting on
Richards shirt tail.

How can an electron accelerate at at open-circuit?
The acceleration is maximum at the current zero-
crossing with the greatest slope. That's at the
center of a 1/2WL dipole.

So are his fantasies new? Or did he have them before and just got a
stump from the patent office?

I truthfully don't remember him being around until lately.

The amazing thing is that his story slowly morphs with time, although it
might be better to say he adds more layers of manure.

And you would know seeing as you are full of it,
Art has posed the question can you answer it or are you
going to duck it as you usually do by making demands
and no offerings.

Hi Chris
The question that goes to nub of Arts claim is
why is adding a time varying field to the Gaussian law of statics
illegal? or to state it another way,
How is it illegal to change a static field into a dynamic field?
can you, will you answer the question or are you just sitting on
Richards shirt tail.

Jaro

I certainly haven't arrived here by sitting on anyone's shirt tails. If
you'd care to read some of the history of this NG you'd see where I come
from.

Your question is not put clearly, although I have seen garbled sentences
like this before in this Usenet group. My first question is: have you
bothered to read any of the respected books on the subject, such as
'Electromagnetics with applications' by Krauss and Fleisch. I suspect if
you had you wouldn't be asking me such a question - it makes no sense! Do I
take it you are referring to Gauss's law for electric fields? Are you aware
that there is a counterpart Gauss's law for magnetic fields? I don't
believe there is such a thing as a single 'Gaussian law of statics' -
someone has made that up!

Gauss's law for electric fields states: the integral of the electric flux
density over a closed surface equals the charge enclosed. This is an
important part of the basis of electrostatics, that is the study of

electrical phenomena caused by static charges, but it applicable at a point in time to any scenario that involves an enclosed charge - which means any electrical conductor, whether it carries a non-moving charge, DC or AC. Gauss's law for magnetic fields states: the integral of the magnetic flux density over a closed surface is equal to zero, and this is an important part of the basis of magnetics, again whether static or changing.

Both of Gauss's laws are embodied in Maxwell's equations and for the normal RF case of sinusoidally-alternating variables a number of different notations can be used, a popular one being phasor notation. As you will know, phasors are vectors that rotate at the same angular frequency but have arbitrary phase relationships and amplitudes - so phasor notation is a compact way of expressing quite a lot. But, in this case, every one of the phasors involved, D the displacement current density, rho the enclosed charge, and B the magnetic flux density, is a variable that alternates with the passage of time. 'Dynamic' variables if you want to call them that.

Neither of Gauss's laws applies directly to strength of an electric or magnetic field but the linkage is the other two of Maxwell's equations based on Ampere's law and Faraday's law, which are both applicable to time-varying fields - 'dynamic fields' if you must.

So ... would you like to put your question more clearly? What do you actually mean by 'to change a static field into a dynamic field' in respect of antennas, where all the electrical and magnetic variables are changing with time, especially the fields? Is this the result of a misunderstanding of the meaning of the word 'electrostatic' - used to differentiate between those phenomena caused by the presence of contained charge and those caused by its movement?

So says the only self-proclaimed expert.
- snip -
>This is not trolling. I am exposing people for what they are and they
>are fraustrated
The only person you're exposing is yourself and not in a good way. It
is extremely difficult to take your arguments seriously or even
understand them given your posts' poor spelling and grammar along with
the abysmal formatting.The spelling variants are understandable, my
schooling started on the banks of the Devon river. Words like
"fraustrated' are something else altogether. That isn't a fat-fingered
error.

Don't blame it one the web interface you post through.Your posts could
be composed and spell-checked in a text editor before the content is

pasted into a web interface. You could
also let
the web interface handle word-wrapping
instead of inserting
seemingly random cr/lf pairs in your
posts.

If you want to be taken seriously you need to present your theories
and arguments in a rational, cohesive manner.

>in their inability to show me as wrong or even having a book that
>states where and why I am wrong.
This is equaled and exceeded by your inability to clearly state and
detail your theories without the use of circular logic. Many times
when a question is asked rather than answer you choose to start a new
thread.

>This is not rambling. Since when is
>the truth rambling?
What makes any of your ramblings the truth? Was your post on GB
standing alone (3 Sept 2009) the truth? You conveniently ignored the
fact that GB's declaration of war came about because Germany had
attacked GB's ally Poland. GB stood beside Poland and not alone.

>If you are an expert take up the challenge in
>terms of academics or consult a professor for an answer Either is
>acceptable for the purposes of debate of what is true or not
>true.Everything I have stated
>stands upon this very point
I have previously suggested that you present your theories directly to
those in the academic community. Why not obtain validation there and
then come back and say 'I told you so'?

>So guys, direct yourselves at the root
>instead of floundering around in a aimless fashion.
>And as far as the size of the audience the bigger the better the
>exposure and the more success I have against those who rely on
>slander. I want this to be as wide spread as possible instead of

Yet you always run to a new thread.

> I am quite sure that many hams around the
>World is following this augument looking for that first person you
>will take up the challenge
>and provide closure with an answer to this very simple question,
>without the fear of recrimination from the group all of which say it
>is illegal.
Did I mention something about spelling, grammar and formatting?

I'm not certain how "many hams around the World is following this
augument" but that number is insignificantly small relative to the
world-wide amateur community. The size of the amateur community is in

turn insignificantly small relative to the world-wide academic
community. You choice of venue is as questionable as anything else.

Gauss's law of statics is enclosed particles in equilibrium. Add a
time varying field to same it becomes a dynamic field in equilibrium
and thus equates with Maxwell's laws.

The easiest way to support your hypothesis is to show a plot or data
table showing how time effects a static field. Frankly I don't know
how you could show any relevant data since the word STATIC means
"unchanging over time" . Applying a time variable to something that is
static is pointless.
Time is relevant to DYNAMIC fields but someone else has already taken
care of that for us.

Jimmie

(written by Unwin)
Gauss's law of statics is enclosed particles in equilibrium. Add a
time varying field to same it becomes a dynamic field in equilibrium
and thus equates with Maxwell's laws.

(written by Chris)
This appears to be paraphysical nonsense, once again.

(a) There are no 'Maxwell's laws' - there are the four Maxwell's equations
based on laws ascribed to the other three authors named above. The term
'eqilibrium' does not feature in, and is not required in, Maxwell's
equations or the laws it is based upon. Radio communication has been based
on Maxwell's equations for more than 100 years without need for
modification.

(b) There is no single 'Gauss's law of statics' as I explained above, and
both of Gauss's laws can be applied to time varying quantities but neither
contains a field.

(c) Both of Gauss's laws are included in Maxwell's equations without
modification - there is no need to 'Add a time varying field to same' - it
is there already in each case.
Once again: Gauss's laws are already applicable to time varying
quantities.

(d) What Maxwell provided was unification of the presentation of the four
equations in differential, integral or phasor form, so the relationships and
linkage between them became clear and they could all be used together to

solve electromagnetic problems.

I think the group is aware by now what I think of the writings of people who claim to know better than Kraus, Jordan & Balmain, Jasik, et al, on the basis of no practical evidence.

The easiest way to support your hypothesis is to show a plot or data
table showing how time effects a static field. Frankly I don't know
how you could show any relevant data since the word STATIC means
"unchanging over time" . Applying a time variable to something that is
static is pointless.
Time is relevant to DYNAMIC fields but someone else has already taken
care of that for us.

Jimmie

I've noted, further down the thread, that the term 'electrostatic' is used
in electromagnetics to distinguish between phenomena that depend on the
presence of a quantity of charge (e.g. electric field strength) and
phenomena that depend on the rate of movement of charge (e.g. magnetic field
strength). Perhaps the 'static' part of the word is a misnomer when the
whole system is alternating at a radio frequency, but it is used widely in
the literature. For example, if you look up the components of electric
field around a dipole you'll find close-in reactive components that are
often referred to as 'electrostatic'.

As always: if in doubt, read Kraus.

Chris

You still did not put a stake in the ground, just walked around the
question and then walked away. One more chance before I place you in
"unsure". Where in Maxwell's equations does it refer to "particles" or
do they have no place in his views on radiation?
What is your call sign or do you prefer to remain as a unknown?

"unsure". Where in Maxwell's equations does it refer to "particles" or
do they have no place in his views on radiation?
What is your call sign or do you prefer to remain as a unknown?

Incorrect; I gave a positive answer to the question. My answer was based on
normal physics and identified what must, therefore, be paraphysical or
nonsense (or both). The equations don't make any reference to particles -
as I'm sure you are aware. As to the views of Maxwell, the person, I
daresay you can make them up to your heart's content without provable
challenge.

I don't much care what category you place me in - you already know how I
categorise people who make up their own versions of physics and expect other
to believe them ... and sadly some appear to!

My call sign, if I have one, is none of your business.

Chris

No, it is not pointless because it enables particles at rest ON
radiators. to be implied. This has been the problem for decades that
has prevented advancement. This extension thus moves away from the
idea of parts removed from the radiator itself. Referring to books is
like saying "all is known". So the question posed is all important
because, if true, it means that a radiator can be any shape size or
elevation as long as all contained is in a state of equilibrium.
Now all avoid the question because they say they don't understand the
word "equilibrium."
So I posed the question to a antenna optimizer where it responded with
a non planar design in equilibrium. Never mind whether it is useable
or not it confirmed the extension given. We have argued for a long
time on a question that contains the word equilibrium rather than
focussing on that which is now revealed. Now along comes this "chris"
who unlike Dr Davis declares he doesn't understand the question(not
equilibrium), tho he has been prolific in advice and insults. So
there has been absolutely no closure on the question thus giving rise
to insults.which all can supply with ease. The question is still
there and does not have academic closure!

when the other disappears.

You are right. Few mans ago I was writting that Gauss law is enough to do
antennas. Of course not this for magnetism.
Static charge produces static electric field and pulsed (in the end of the
antena) alternating field. It is radiation. For me there are ether vaves.
For Art photons or something else.

O.k. So the thread as posted in the title is now closed. On the
question on the Gauss extension this is not understood so that is also
now closed. Insults? Well they can go on for ever as this is the main
attraction for its members.

What do you think gives you the power or the right to close a thread - is
this something written in the Usenet 'code of practice'? Surely, in
practice it will continue until all aspects of discussion have reached their
conclusions and more interesting threads have appeared.

Do yourself a favour Art, visit a technical library, read and try to understand the real physics on which radio communication has been based. If you have problems with any of the parts that are well documented then there will be plenty of folk here who will be willing and able to illuminate, including some with less time on their hands than myself who don't post very often but have extensive knowledge. I think you will find it fascinating how intelligence can be passed between two points in space without any need for the passage of matter between them - all puns accepted!

Chris

It is not easy to understand you. Math says that "the derivative of a sine
wave is 0 at the peak," next that it is not true and next that math is
always right.

Electrons flow free in feed line and are compressed in ends. After short
rest they come back to supply unit.

Accelerate and deccelerate. It is only possible with compressible electrons
(as electrn gas). It is impossible in Heavisde's hydraulic analogy.

Hi Chris,

This mistake is being compounded daily, so it seems. The "absence" of
current on any particular portion of the antenna is the superposition
of two currents flowing - hence the term "standing wave antenna."
Hence there is something of a paradox that where two currents reside
(the metal elements are continuous and conductive) it is said no
current flows. There is a correlation between this superposed
solution and the pattern of the far-field pattern but that does not
lead to the conclusion that there is no "acceleration" of charge at
the ends. After-all, the abundant alternating voltage at those same
ends is also charge, n'est pas? It could be as easily argued that
superposed voltage nodes also define the pattern of the far-field
pattern.

Maxwell did exactly that and called it Gauss' Law (Gauss did not do it in his law that he did not call Gauss' Law). History came along and uses the same name for two laws. Maxwell acknowledged Gauss' contribution for statics and applied time to them to arrive at dynamics (and honored Gauss by naming his dynamics Gauss' Law). So History and Maxwell have long observed TWO Gauss' laws - each distinctive as the first being static, the second dynamic.

Art has never gotten past this historical hiccup.

At last, at last. Richard has turned around after giving a drubbing to
Dr Davis and now
comes around to stamp the extension as legal. In fact he states it was
always like that!
Now will the group as a whole follow his lead and do a spin in
thinking? You can, you can
add an extension of a time varying field to a static field to turn it
into a dynamic field.
I will leave the group to turn to Richard and question his present
motives and advise him to reverse his new posture

Well that's not correct - you can't 'do antennas' with Guass's law for electric field alone. You've already been told that radiation requires acceleration and deceleration of charge, that is, alternating current, which creates a magnetic field and the strength of this field is related to the amplitude of the current by Ampere's (circuital) law, which is the basis for one of Maxwell's equations.

In fact, it takes current (i.e. movement of charge) to create potential differences so, even if you are encumbered with 'electrostatic blinkers', the current comes first and is more fundamental.

Chris

Cecil, After all this time of taking no decision who lost itat the
last minuite
Skin effect refers to current flow along the aluminum. It even shows
witness of this by inlaying circular grooves in its surface. This by
the way is a measurement tool in non destructive measurement. This
current method provides resistive impedance which signifies energy
lost. You then have another component which is termed radiation
resistance which points to energy applied to to create radiation by
the launching of the particles. When you do your fancy playing with
EZNEC you will notice that as the impedance goes down the radiation
increases. It will continue to do so while the impedance goes down as
a result of more current flowing outside the aluminum When you get to
the point when the impedance is zero it shows that all applied
current has been applied outside the aluminum which is now not
carrying ANY of the applied current. WOW!
You can also apply even more current of which all will still go to the
external sleeve of
particles to increase radiation and still no increase in current flow
in the surface of aluminum, even tho the impedance may go into the
negative quadrant. You also stated that applying a time varying field
is an example of typical failures! No idea where that comes from. Now
with reference to current flow in the particle sleeve. We had an
extensive discussion as to how the circuit of a half wave vertical
antenna was formed. At that time I was adamant that it must be a
closed circuit and suggested that return flow was thru the centre of
the antenna. Another brou har ensued with the implication was that
both the upward and downward travels of the applied current was on the
same skin deep surfaces! Very wierd. One of your past disagreements
with the group extended beyond the 1000 posts so I am certainly not
going to take on the debate mode with you.
Have a happy day.

> Richard Clark, KB7QHC

Well, the moment of a section of a dipole is proportional to the average net current on it and it's the integral of the moments at a point of inspection that yields the radiation pattern. In my simplistic way of thinking, if the moment of the end sections is zero, or as close as makes no difference, then there's no contribution to the pattern from there, so there's no radiation from there. Someone else who posted here a while ago used the term 'unopposed' current which is useful because it's the basis of why twin-wire transmission line, driven differentially, is a poor radiator - put another way, the moment at any point is close to zero. Alternatively, if there's no radiation from a 'source' then there can't be any unopposed current there.

I wouldn't contradict what you say about there being a collection of charge at the ends of a dipole during each cycle, especially when it has added

capacitance (e.g. a 'hat' or the top of a 'Tee'), but the current in a symmetrical hat is fully opposed and, as I noted before, the current at the end of the conductor must be zero - by the definition of conduction.

I believe there is danger in trying to relate radiation to voltages rather than currents, arguing that displacement current causes radiation. Therein lies the fallacy of the CFA, E-H antennas, and associated efforts at re-writing of Maxwell's equations, which are all being demonstrated as bunk. Also, this appears to be the basis of Mr. Bialek's lecture series. If you wish to argue 'that superposed voltage nodes also define the (pattern of the...sic) far-field pattern' then I won't stand in your way ... but I probably won't believe you.

* No, it has nothing to do with tipping. The electrostatic field strength close to a conductor is reduced by giving the conductor a large radius of curvature: it's greatest between points and least between parallel plates. Read Kraus; Electromagnetics!

Art, below to help you analyze your belief is a link to the calculated radiation efficiency for a system with a perfect, base-driven, monopole radiator using an r-f ground better than that used by most AM broadcast stations.

The system is brought to resonance with a loading coil. The feedpoint impedance is 4.1131 +j0 ohms, of which the radiation resistance component is ~ 0.1 ohm.

So if, as you write, reducing feedpoint impedance increases radiation, what do think accounts for this extremely poor system efficiency (2.75%), compared to the ~ 95% system efficiency typical of a 1/4-wave monopole using that same r-f ground?

Hi Chris,

I have already offered that what you say above is not disputed. I
merely add that it is not the only perspective and says nothing of the
"absence" of current throughout the entire radiator.

> In my simplistic way of thinking, if the
>moment of the end sections is zero, or as close as makes no difference, then

That was the logical basis for Art's claims of length efficiency:
those portions that did not support current (read contribute to
radiation) were thus ancillary (redundant as the Briticism would go)
and unneeded. Art would then expand this logic to perform his Ritual
Antenna Bris and lop off a portion to reduce the length (increase the
efficiency). I've already commented on this reductio ad absurdum.

Far field patterns are created from the phase relationships and time
relationships, and distance relationships (all the same thing,
mathematically) from all points of the radiator to any single point of
the characteristic lobe. In the teachings of radiation as light, a
wave front can be considered to be an infinite number of points of
radiation along a curved line (that front).

Interference (with its product being the shape of a lobe) is the
combination of all their phases, distances, and times.

This is not the same sense of current in a single wire that gives rise
to a structure known as a "standing wave antenna."

If you ran a twin line up into the air to an open connection, then you
would have two closely space radiators. The open would enforce a both
a longitudinal and transverse standing wave. They would both radiate

like twin fire hoses. The key point here is that in the distance of
their separation, that distance is an incredibly small fraction of the
wavelength they are radiating. Their two currents (the standing waves
on each wire being immaterial) impose an 180 degree relationship
throughout their entire length. Both waves' phases, distances, and
times cancel to within the degree of that space of separation. This
is very easy to demonstrate by observing how they become efficient and
productive non-canceling radiators as you draw them apart to form the
V antenna. The only thing that has changed is the distance which
imparts a phase (or time, or distance - all the same thing
mathematically) shift apparent at a great distance. They will still
have the same SWR along their length, and the same currents (apart
from what is imposed through the radiation resistance).

Well, to this point there has been no discussion of end loading.
Doesn't matter, all the key issues are discussed above.
>
>I believe there is danger in trying to relate radiation to voltages rather

This is an engineering shorthand. It works with great precision. But
the simple fact of the matter is there is no current without a
potential gradient. Radiation could as easily be described by it.
Without regard for patterns, radiation is a function of Ohm's law and
we have three variables there. You cannot ignore any element or
assess some distinction of one at the cost of the other(s).

>Therein
>lies the fallacy of the CFA, E-H antennas, and associated efforts at

>probably won't believe you.

So I gather. It is merely a shift in perspective of conventions, not
an up-ending of them. You may note that none of my discussion above
demands any new physics, nothing new in math, no novel methods. I've
used only two wires both close together and drawn farther apart under
the most simple of terms to reveal on one hand a transmission line,
and on the other hand a V antenna. The math of phase, distance, and
time is drawn from NEC; or rather, NEC leans heavily upon it and drew
it from Optics and I state my case in the strict terms of a method of
moments.

To cut to the chase: The full length of the radiator contributes to radiation and the evidence of this is found in any characteristic lobe displayed in the far field.

In practical and provable terms, how much of that characteristic, far-field radiation pattern can be attributed to the linear, unloaded, center-fed dipole radiator lengths as exist less than ~10% distant from the endpoints of that dipole?

Just wanting to learn.

The math behind this has been terribly abused by Cecil in the past,
but we shouldn't let that poison the well. It is based in optics, a
field that predates RF by several centuries.

"... S1 and S2 are two point sources of light each
emitting a sinusoidal wave of the same angular
frequency omega. They have position vectors r1
and r2. The field point P where we evaluate the
intensity [flux density] has position r. The electric
field at P resulting from the two sources is assumed
to be of the form....
"The total relative phase Psi0 between the two waves
at P thus consists of two parts: a part Phi2 - Phi1
coming from the relative phases at the two sources,
and a part -Dell coming from the different
retardation in phase suffered by the two
beams resulting from the propagation
from S2 to P and from S1 to P.
"An important special case occurs when
A1 == A2. Then we can write
I = 2ï¿½I1ï¿½(1 + cos(phi2 - phi1 - Dell))"

Every point along the radiator is considered to be a point source with
the same frequency. However, each point is not at the same phase by
virtue of its distance from the feedpoint and its distance from other
points. Each point is not at the same distance from P (a point in the
far field) which gives rise to a retardation of that altered phase.
Thus the phase accumulates over two distances: one from the excitation
source to the point on the radiator; and, two, from the point on the
radiator to the point of the lobe where we are observing all of the
effects of the combined illumination from all point sources along the
length of the radiator. The extract above speaks to the contributions

of only two points, an antenna comprises many, many more.

I will add here that the intensity variable now draws in the discussion of the superposed forward and reflected currents. This is the remaining part of the analysis which is more instructive for your very simple example. Clearly, from a very small dipole to a half wave, there is little variation in the far field pattern and it is appealing to infer that the differences in length suggest that that additional length suggests nothing is going on in the ends. However, when we add only a slightly longer length (by proportion*), this negates the appealing suggestion. The superposed current distribution change accounts for this and we are still talking about simple linear elements (and there is still zero current at the ends).

If we were to succumb to the argument of "length efficiency" as offered in the practice and Art of Antenna Bris, then the additional gain of that proportionate smaller length addition would have been lost to that invalid proposition.

The NEC method of moments is by definition the application of the formula above to the middle of EVERY segment to EVERY point in three space. The resulting curve is an abstraction of that fog of numbers that is reduced to a planar curve (or to a solid model in the 3D representation).

[* What is this proportional and proportionate mean? For a dipole of 0.05 WL to a dipole of 0.5WL, the far field change for that 10:1 variation is negligible. However, for a dipole of 0.5WL to a dipole of 1.25WL, the far field change for that 2.5:1 (a smaller proportion) variation is very noticeable.]

You assume: "The value for conduction electrons / m^3 matched the number of
atoms / m^3, within the error of the copper's density"

It is not true. So the speed for steady current is bigger.
But in antennas is oscillating current. To describe the electrons one must
take into account acceleratin and compressibility. Speed at small movements
can be small but acceleration huge.

"Every point along the radiator is considered to be a point source with
the same frequency".
But the intesity of radiation is not the same. Electron at the end of the
open circuit are extremally compressed. Intensity of radiation is
compression dependent. Of course radiation means alternate electric field
(Art's "Gauss law with time").

Antenna is the last part of the open circuit. If it has the half wave or
less such dipole antenna has only one intesive source of radiation on one
radiator.

The both (0.05 WL to a dipole of 0.5WL have only the two sources at the both ends.

> However, for a dipole of 0.5WL to a dipole
> of 1.25WL, the far field change for that 2.5:1 (a smaller proportion)

Each "long wire antenna" has additional sources for each 0.5WL.

"The full length of the radiator" means the "vissible" and spaced part of feeding line. Yor: "If you ran a twin line up into the air to an open connection, then you would have two closely space radiators."

Step by step and the discussion should end with the full agreement (I am sure).

Thanks large radius we have radiation not sparks. The electrostatic field
strength may be much stronger because we can use very high voltage.

Art Unwin wrote:
> Skin effect refers to current flow along the aluminum.

Actually, it is more complicated than that. Since
the current impulse travels at the speed of light,
the current impulse energy transfer necessarily involves
photons. Note there is no current impulse traveling at
the speed of light under steady-state DC conditions
which is the only kind of current being carried 100% by
electrons. Any current, e.g. RF current, traveling at
the speed of light, involves photons, even the DC impulse
current.

> When you get to
> the point when the impedance is zero it shows that all applied

> carrying ANY of the applied current. WOW!

It is true that one can set EZNEC to lossless conditions but
one cannot do that in the real world. Aluminum and copper
are only ever lossless at superconductor temperatures.

> You also stated that applying a time varying field
> is an example of typical failures! No idea where that comes from.

Me either since I don't remember anything about "typical
failures". What I said is that the electrons excited by
HF+ RF energy move hardly at all. It is akin to tossing
a stone into a still pond - the water molecules (carriers)
move hardly at all except up and down.

> Another brou har ensued with the implication was that
> both the upward and downward travels of the applied current was on the
> same skin deep surfaces! Very wierd.

Again consider tossing a stone into a still pond. When the
waves reach the shore, they are reflected thus forming
standing waves on the water. Again the water molecules
move primarily up and down, moving hardly at all in the
direction of propagation of the forward and reflected waves.

Let me make myself quite clear on this point before the thread closes.
My position is that a radiator must be 1WL to achieve equilibrium.
When considering a
1/2 wave vertical one can only make it a closed circuit of 1 WL is by
adding a ground plane
rather than assuming that we have conflicting charge directions on the
surface of the 1/2 WL.
We now review the circuit (tank circuit) that applies to radiation. We
now accept that particles do rest on diamagnetic surfaces per the
Gauss extension. In fact, this surface or sleeve of particles is so
tightly formed that it has the hoop stress of a arbitrary boundary
such that nothing is removed from the diamagnetic material itself. In
the case where a particle is driven away from this border its place is
immediately taken up by one of the billions of particles floating
around looking for a diamagnetic place to rest.
We can now see that current applied to a radiating element splits into
two paths in parallel
One leg is in the intervening space between the particles and the
diamagnetic material and the other leg IN the surface of the

diamagnetic material called skin effect.
A computer program only recognizes the diamagnetic element such that it only points to the impedance presented by that separate current track .
Thus with increase in radiation the impedance referred to by the computer is SOLELY
of that presented by the diamagnetic material. Thus when the program states zero impedance it is stating that no current is being applied to the diamagnetic material
and where all current is routed to the arbitrary boundary consisting of tightly bound particles.
The concept of extreme cooling for zero resistance is not required when no current is applied! All the current is now being carried by the arbitrary border where all forces can be accounted for since there are no losses incurred! Of-course the program itself leaves the operator to sort this out because it did not supply a complete circle of energy flow by ignoring the current applied to the particle sleeve or boundary, where the energy lost in the
programs element is not supplanted with the energy gain of the arbitrary border! This suggests that somewhere in the program the positive and the minus signs were accidently interchanged. If the programmer had recognised the existance of the Gaussian border
he would have the provided the means of energy transfer to it and thus fully abided with the concept of equilibrium.

And why is your "equilibrium" needed?

Note that antennas of every length produce very efficient radiation
from all of the r-f current that can be made to flow on them.

For a given r-f source and antenna, maximizing that current is a
matter of providing a non-reactive match of the antenna feedpoint
impedance to whatever is connected there.

There are good reasons to prefer one antenna length over others, such
as the radiation pattern produced, or the ease of providing a good
match to a transmission line.

But "equilibrium" is not one of them.

The electrons are NOT the EM photonic waves. The electrons
are the carriers for the EM photonic waves. It is NOT the
electrons that have the transversal wave characteristics.
The movement of the electrons in the conductor is indeed
longitudinal but that movement is close to infinitesimally
small at RF frequencies. The movement is more like an
oscillation in place.

Richard Clark. KB7QHC wrote:
"Several were astonished (as I have already mentioned) to find that his antenna design had reflector (the new and improved model had two) elements that were shorter than the driven element and the director elements longer."

Of course no one could prove for Art how his antenna worked. They weren`t gifted with his type of genius.

As Terman says on page 906 0f his 1955 opus:
"The fact that a parasitic antenna placed close to a radiaring antenna can be used either to reflect or to direct the radiated energy can be taken advantage of to obtain a compact directional antenna system. A simple example is shown in Fig. 23-39 where the reflector length is such that it is resonant at a lower frequency than that being transmitted, while the the director length is chosen so that it is resonant at a higher frequency than is being transmitted."

Most everyone in this newsgroup has tried the classic Yagi arrangement and knows that Terman has it right.

Art`s patent does not prove Terman wrong.

Best regards, Richard Harrison, KB5WZI

"I`d be willing to bet, say, 100 UK pounds that Professor Unwin can`t create an antenna in hardware that radiates isotropically, that is over the whole sphere within let`s say +/- 1 dB with respect to any chosen (but constant) polarisation."

Many would bet just as Christofire.

An isotropic may fit Art`s definition of "equilibrium" but according to Terman it is impossible. Terman`s footnite on page 871 of hid 1955 opus says:

"An isotropic antenna produces waves that are of equal strength in all directions. Although an isotropic radiator of coherent waves does not exist because it cannot satisfy Maxwell`s equations, the properties of such an imaginary antenna are easily visualized, and the concept of an isotropic radiator is often found useful to the analysis of antenna systems."

My money is on professor Terman.

Next I wrote: "They move along the eliptic trajectory. The longitudinal
>> component is large(r) than the transversal"

So "They" The water molecules not "Electrons"

It is very important to know that the water waves are not transversal.
Everybody who know that understand that in reality no pure transversal
waves. In reality are waves which interfere.

I do not know what are movements of elecrtons in conductor but in air
(lightning) they oscillate with RF frequences and that movement is not close
to infinitesimally small (kilometers).

So I will start "Mr. Bialek's lecture series" as a new topic.
The first will be on a "standing waves". A will try to explain the paradox:
"Hence there is something of a paradox that where two currents reside (the
metal elements are continuous and conductive) it is said no current flows
(R. Clark).

Unfortunately, the discussion is not about lightning
but is instead about the "movements of electrons" in
an antenna "conductor" about which you "do not know".

Incidentally, the electrons energized by lightning do
indeed emit broad spectrum photons, i.e. EM waves.

No NET current flows. The forward current associated with the
forward EM wave is moving forward at the speed of light in
the medium. The reverse current associated with the reverse
EM wave is moving backwards at the speed of light in the
medium. When the forward current amplitude equals the reverse
current amplitude and is 180 degrees out of phase, the net
current flow is zero. 1/4WL away, those equal currents are in
phase and add. If the net current is measured at the maximum
(anti-node) point, it can be divided by two to obtain an estimate
of the magnitude of the forward current at the node point where
the net current is zero.

The forward current at the ends of a 1/2WL copper dipole is
approximately 95% of the forward current at the feedpoint.
The reverse current at the feedpoint is approximately 95%
of the reverse current at the ends of the dipole. It's a
STANDING WAVE ANTENNA! That ~10% decrease between forward
current and reverse current at the feedpoint is caused by
radiation "loss" and I^2*R loss in the antenna.

The SWR on the antenna element is approximately 20:1 at the
feedpoint. It is a STANDING WAVE ANTENNA! Most of the net
current on the antenna is in the standing wave and cannot
be used to measure the delay through the wire or through a
loading coil because the current phase changes by only about
2-3 degrees in 90 degrees of wire. The standing wave contains
about 80% of the steady-state energy on the antenna. Only about
20% of the steady-state energy/sec is lost to radiation and
ohmic losses.

One can prove such for oneself. Set up a low 10m 1/2WL dipole
with current probes at the 30 deg (x) and 60 deg (y) points.
One will not be able to detect more than about a degree of
phase shift in that 30 degrees of standing wave antenna.

8ft 2ft 2ft 2ft
------------------------fp-------x-------y--------

Why would anyone expect that if the 30 degrees of antenna
is replaced by a loading coil that the delay through the
loading coil could be measured using standing wave current
phase on a standing wave antenna?

Do you really mean relative phase of the outward-travelling currents at x and y? If so that sounds terribly hard to measure: you'd need a pair of directional probes that you could hang on the antenna without affecting its current distribution. Or do you mean the amplitude of the standing wave pattern of current, in comparison with an idealiesd sinusoidal distribution which has zero at the end? If the latter, 'phase shift' is probably not the correct term.

If you really do mean the relative phases, but as measured with non-directional probes then even that would be hard to interpret given that there are superposed outward- and inward-directed (i.e. reflected) components of current on the dipole limb.

Or am I missing something?

2116. Standing waves

Newsgroup: rec.radio.amateur.antenna
Date: 2009-09-17 17:15:56 UTC
From: Szczepan Białek <sz.bialek@wp.pl>
Message-ID: <h8tfnv$b45$1@node1.news.atman.pl>
Source record: 13078

Frankly speaking no standing waves. Waves always travel. In air travel the pressure pulse. When the two waves travel in opposite directions they interfere. See: http://en.wikipedia.org/wiki/Kundt's_tube
"The sound generator is turned on and the piston is adjusted until the sound from the tube suddenly gets much louder. This indicates that the tube is at resonance, which means its length is a multiple of the wavelength of the sound wave. At this point the sound waves in the tube are in the form of standing waves, and the amplitude of vibrations of air are zero at equally spaced intervals along the tube, called the nodes."

Between the nodes are places where the amplitude is doubled. So the places with doubled amplitude are standing. Pressure pulse travel.
In antennas is electron gas. The first place where the doubled amplitude (amplitude means voltage or electron density) appear is end of the radials. The next is halve wave apart from the end. Such places radiate strong electric waves. They are the source of radiation.
Of course the next source is weaker because some part of energy is radiated. But such is stronger than the trawled source (normal voltage pulse)

If antenna has only one source it is omnidirectional. If two or more is directional because the waves from different sources interfere.

The halve wave dipole has the two sources. The next two appear than a dipole is longer than the wave length.
So that what R. Clark wrote is obvious: "[* What is this proportional and proportionate mean? For a dipole of
0.05 WL to a dipole of 0.5WL, the far field change for that 10:1 variation is negligible. However, for a dipole of 0.5WL to a dipole of 1.25WL, the far field change for that 2.5:1 (a smaller proportion) variation is very noticeable.]

The above is the antenna with the Helmholtz' pressure wave.
Could anybody describe the antenna with the Heavisde's TEM waves?
In a few words. Do not send mi to library.

Exactly!

> Or am I missing something?

Nope, you are not missing something. But some reasonably
intelligent and educated people have used non-directional
current probes on loading coils in standing wave antennas
to "prove" that, e.g. the delay through a 10" long, 2" dia,
10 TPI 100 uH 75m loading coil is only 3 nS with a VF of
about 0.3.

http://www.w8ji.com/inductor_current_time_delay.htm

http://www.w8ji.com/mobile_and_loaded_antenna.htm

"Both W7EL and myself made independent measurements of current
in small loaded antennas. These measurements demonstrate the
'missing electrical degrees' in an antenna has nothing to do
with current distribution in the coil."

http://www.w8ji.com/inductor_operation.htm

http://www.w8ji.com/RRAA_post.htm

W7EL wrote: "and this one, posted by Cecil on that same
group on Jan. 12:"

W5DXP wrote: "Roy's data clearly illustrates
the phase shift through the coil. ARCCOS(Iout/Iin) gives an
estimate of the phase shift (assuming forward current and
reflected current are of equal magnitude). In Roy's experiment,
Iout/Iin was about 0.95. ARCCOS(0.95) equals 18 degrees, an
approximation for the phase shift through the coil."

W7EL goes on to try to discredit my above argument.

However, the following web page indicates that the 3 nS
"measurement" is off by a magnitude and that the actual
delay through the above coil is closer to 30 nS
calculated from the "axial propagation factor" and has
a VF of about 0.03, 10 times slower than the 3 nS assertion.

http://hamwaves.com/antennas/inductance.html

P.S. This argument has been going on for about 6 years.

2120. EZ-NEC seems not to match the Antenna Book?

Newsgroup: rec.radio.amateur.antenna
Date: 2009-09-17 18:59:39 UTC
From: Antonio Vernucci <vernucci@tin.it>
Message-ID: <4ab2871a$0$1108$4fafbaef@reader1.news.tin.it>
Source record: 13082

In the 1976 edition of the ARRL Antenna book, at page 147 I see a graph (Fig. 4-37) showing the gain of a two-element array consisting of a driven element and a self-resonant parasitic element (i.e. same length as driven element, no de-tuning).

The graph shows gain (in the two orthogonal directions) as a function of spacing. For spacing = 0.14 wavelength, the graph shows a bi-directional gain of about 4 dB (and then a front-to-back ratio of 0 dB).

Unless I did something wrong, on EZ-NEC the same array with 0.14 WL spacing shows a free-space zero-elevation gain of about 6.4 dB in one of the two directions, with a front-to-back ratio of about 10.5 dB.

Which of the three is wrong: Antenna Book, EZ-NEC or me?

BTW: as far as radiation resistance is concerned, EZ-NEC gives about 17.9 ohm at resonance, against the nearly 21 ohm shown by the Antenna Book.

Re-thinking on the results, the gain difference is probably due to the fact that the ARRL Antenna Book graph gives dBd, whilst EZ-NEC gives dBi.

But what about the great difference in front-to-back?

Tony I0JX

The problem I immediately see here is that you're probably interested
in electromagnetic radiation, not just the electric field. The
result, as I see it, is that the rest of your discussion is based on a
completely false premise. But see below.
...
> The above is the antenna with the Helmholtz' pressure wave.

Others have tried to describe radiation from linear antennas in
reasonably simple terms. One of the best I know is Joseph Boyer's
pair of articles from May and June, I think it was, 1978 "Ham Radio"
magazine: "The Antenna-Transmission Line Analog." It's a non-
mathematical work; it will leave you with answers with not a lot to
back them up, but they do match what we observe, as far as I
understand it. I have these as a PDF, along with a fairly important
section from a book referenced by the articles.

Cheers,
Tom

More study is needed on your part, S*. Consult the textbooks of the authors that already have been listed, and quoted here.

Your unproven, personal opinions are not sufficient to support some of the statements you post-- which accounts for the "negative" comments responding to them.

Every single real-world antenna in existence has more than one source along its length that contributes to its radiation pattern, and therefore has some directionality.

Your study and accurate understanding of the works of the authors mentioned will prove this.

The problem is that all forces are not accounted for per Maxwell
requirements!
In your case magnetic energy remains with the radiator which is a loss
that is unaccounted for ! This loss does not occur with a diamagnetic
materials. Very simple my dear Watson.
When you use computer programs in conformance with Maxwell's equations
you can expect 100% efficiencies not the "close enough for horse
shoes" type responses.
If a design is planar it just cannot be 100% efficient as when all
forced are accounted for.
When you obtain 100% efficiencies then other surprises enter the
picture which allows the use of smaller volume antennas than those
known to the present state of the art. Not to be seen in books by
Krauss, Balmain, Terman and others because they were not just aware of
it and not that it is an error. There is no real volume restriction
with respect to antennas with today's knowledge. I found that out by
making a resonant directional antenna for all the TOP band that fits

into my rotor on the tower. It is very rare in Classical Physics that statements made are not subject to revision by following generations who are able to climb on the shoulders of others such that hidden things can be seen when the vision of prior generations begin to dim.

OK Cecil, I can see there's plenty of scope for argument in this field of endeavour. It must be difficult to avoid influencing the current distribution when any sort of current probe (e.g. torroidal transformer) is placed around a dipole limb but I suppose it is possible with adequate choking of its secondary connections. I'm not sure a 'grab test' is sufficient to prove no influence on the current distribution, even if it does suggest the secondary connection isn't 'hot' to RF. Then the assumption of equal forward and reflected travelling waves of current can't be right, because that would imply no radiation (it would be true inside a co-axial cavity resonator) - but you probably have that covered by now.

As for the precise behaviour of inductors in respect of coupling between turns and its effect on velocity of propagation through the device, I can see there's endless scope for variation/argument there as well. I have encountered something similar in my work, in respect of Litz wire/cable - I reached the conclusion that inhibition of transverse current was the only reliable benefit; all the other stuff about skin effect in individual conductors (when they're coupled to one another inductively and capacitively) seems questionable!

I certainly wish you good luck in getting to the truth about these matters.

Chris

What do you mean by (self) resonant?

Physics shows that NO radiator as small as fits into the rotor on your tower, by itself, could possibly be self-resonant at "TOP band."

You've been done for a looong time, Art. You just don't realize it yet.

Your patent attempt proves nothing. It's bad physics, and even with the clueless dips that work in the patent office you are still being rejected. It's gotta be pretty useless if they won't approve it.

It is very normal for them to request changes. Obviously you have
never filed a patent
or done anything that would warrant one. Why not pair up with David
and write one yourself
or do you have some already? No that can't be, otherwise you would be
aware of office actions as it goes on all the time. So is it you who
is now Master of the group and self esteemed expert that we all now
have to follow? Your insults are as good as Davids was!
Either way I'm done for a while.

> be right, because that would imply no radiation ...

Of course you are right. But the forward and reflected waves
are equal at the ends of the dipole. At the feedpoint of a
1/2WL dipole the reflected current is only ~10% down from
the forward current so the equal current assumption through
the center loading coil is definitely only an approximation.

The question remains: How can the current on a standing wave
antenna, known to change by only 2-3 degrees in 90 degrees
of antenna, be used to measure the delay through a loading
coil installed in the standing wave antenna?

Incidentally, the equal amplitude and opposite phase of the
forward current and reflected current at the ends of a 1/2WL
dipole is the reason that the ends don't radiate much. The
two currents are acting like transmission line currents and
thus any radiated fields tend to cancel because of destructive
interference.

The forward current and reflected current are in phase at
the feedpoint. Their fields interfere constructively and
thus radiation is maximum at that maximum current point.

"If antenna has only one source" means the monopole antena (the second
source is "graved")
"The halve wave dipole has the two sources" means "dipole has visible the
both ends".
O.K now?

I assume from what you posted before that you meant to write
"in a monopole antenna there is one strong source on the END..."

Could you please post the reason(s) you think so?

Note that only the change in current and charge, over time,
produces EM radiation. At the top of a monopole, and at the ends
of a dipole the net current is almost zero -- so those locations
generate very little of the total EM radiation from these antennas.

RF

> "The Antenna-Transmission Line Analog."

It's a good analog. For instance a 1/4WL open-wire
open-circuit stub made with resistance wire with
a resistivity of 0.0000021 ohms-m has a feedpoint
impedance of 35 ohms according to EZNEC.

The current distribution is a close approximation
to a 1/4WL monopole. The additional resistance
over copper approximates the energy lost to
radiation in a 1/4WL monopole.

Since the forward current and reflected current are equal
in magnitude and opposite in phase at the ends, they act
like transmission line currents and the magnetic fields
cancel at the ends. They are in phase at the feedpoint -
hence the maximum radiation at that point.

Each dipole has visible the two radials (sometimes end parts of the
transmitting line). Each radials has the one strong source at the end like
the Kundt's tube. See: http://en.wikipedia.org/wiki/Kundt's_tube
A dipole has the two radials so it has at least the two strong sources.
Only the two if it is shorter then WL. If it is longer than WL then appear
the next sources on the both radials at each 1/2WL from the end.

I will be absent till Monday evening.

You go into details.
In the Gas Analogy the monopole antena is exactly like the Kundt's tube.
See: http://en.wikipedia.org/wiki/Kundt's_tube
A dipole has the two Kundt's tubes.

Hi Richard,

The entire radiator radiates, not just portions of it. The phase,
time, distance relationships along the length contribute to a myriad
of characteristics, but they are not separable from the complete
contribution.

Analogy is a false arguement. In the car-seen-at-a-distance analogy,
this proves that only midgets or pygmies drive cars because we are too
big to fit into such small things seen in the distance.

Using the method of moments, each segment contributes
radiation proportional to the net current in the segment.

Heaviside did the Hydraulic Analogy. All is exactly the same like in the
fluids mechanics.
Next the electrons were discovered. Automatically Heaviside is a history and
the Gas Analogy is in power.

"Exactly" makes it very, very easy to show how an analogy fails:
Describe the laminar flow in terms of
the Reynolds number for
the interface between RF and a Biconical Antenna
and
the interface between RF and a thin wire Antenna.

If you do not understand
1. the terms of fluid mechanics and/or
2. cannot complete this request, then
your analogy has failed.

I won't wait for that obvious failure. This is several steps above
your pay-grade. So, you should really attempt to work on first
principles rather than rummaging in the attic for impressive artifacts
of science. The musty chestnuts you find would poison a dog.

neither analogy is 'right'. they are useful in limited circumstances to
demonstrate some basic pressure wave physics to young students. but neither
one properly reproduces electromagnetic waves.

This is when all current is transferred to the particle encapsulation
and no current travels
in the radiator carrier ie Radiation resistance is 52 ohms

Cecil, W5DXP wrote:
"The forwerd and the reflected current sre in phase at the feedpoint and thus radiation is maximum at that maximum current point."

Exactly. The reflected current has made s round trip of 180 degrees plus the reflection has added another 180 degrees for a total of 360 degrees or back in phase with the forward current at the feedpoint.

At the open circuited ends of a resonant antenna there is almost double the forward voltage but zero total current due to cancellation of the dorward and reflected currents at the open circuit. At the open circuit in the wire, all the energy in the wave is transferred to the electric field.

The relationship between the input power of a given antenna and the strength of the far electromagnetic field which it will produce depends among other factors the length and shape of the antenna.

Best regards, Richard Harrison, KB5WZI

Hmm, I think I'd start with a very long K1FO yagi, say 50 elements.
Maybe even extend one to 100 elements to getting very fine details.
Then we look at the longitoodordinal current along the horizontal
element by element. I'll have to work on it a while though.

What are you thinking?

I am thinking that Stefan by lacking a demonstration of this
employment of his own chosen metaphor displays a vacuum in two subject
areas. As it stands, he stumbles through the nuances of RF. Instead,
he is trying to extrapolate them through a second subject, where, of
course, he tumbles over the nuances of fluidics.

The best we can expect is for him to haul a book to the nearest Xerox
and lean on the copy button to produce a snow job. The deepest
impression he will get of that intellectual experience is a paper cut.

Hello,

Thanks for help.
In my 70's now, and not all that sharp with this "stuff" anymore.
Really appreciate the help.
Plumbing my antenna and radios together is for me now a fairly big job, and
I would like to do it only once

Trying to decide on the "best" pushbutton switch for me, per my previous
post below.

There sure are a lot of offerings around for A/B pushbutton switches these
days.
All real cheap, hence my concern and questions.

Frankly, I don't think my application calls for the relatively expensive
Alpha Delta, Daiwa, etc. units,
as I do receiving only.

As I will be switching two receivers into a single Scantenna vhf/uhf
receive-only antenna,
I would like to get the one with the least loss, decent construction, etc.

Need something from HF frequencies to a true 2.0 GHz

Jeff; the one you suggested apparently comes out of Eagle Aspen Company,
and/or Pro Brand.

For the one you suggested: is it the consensus of most folks that this is
the "best" available these days ? (Is it "better" than the Grove offering,
which I was seriously considering ?)

Are there even better ones available for, e.g., under $ 25 or so ?

Any thoughts would be most appreciated.

Much thanks,
Bob

"A more modern
version is commonly available from CATV and Satellite TV vendors:
<http://www.sadoun.com/Sat/Products/Perfect/Perfect_Vision_A_B_Switch.htm>
$5/ea plus tax and shipping."

Regarding this pushbutton antenna switch that Grove offers:

http://www.grove-ent.com/SWC01.html
$19.95 SWC01

Was wondering if anyone is using it, or has any opinions on it ?
Sure is cheap enough.

They claim "usable" up to 2.0 GHz.

My application would be HF thru the vhf/uhf scanner frequencies,
BUT Receiving only.

2169. Resaonance and minimum SWR

Newsgroup: rec.radio.amateur.antenna
Date: 2009-09-19 16:03:25 UTC
From: Antonio Vernucci <vernucci@tin.it>
Message-ID: <4ab500ce$0$826$4fafbaef@reader5.news.tin.it>
Source record: 13031

Reading here and there that the signals of the on-going DX-expedition to Glorioso Island are generally very low, I got the curiosity to simulate the so-called "spiderbeam" antenna they are using (sized for the 10-meter band) on EZ-NEC.

Doing that, I obtained an unexpected result. The simulated antenna shows a clear SWR minimum at 29.0 MHz where impedance is 76 + j32 ohm.

I then checked SWR across the 24 - 34 MHz range with the following results:

- going up in range 29 - 34 MHz, the reactance steadily increases (+334 ohm at 34 MHz)

- going down in range 29 - 24 MHz, the reactance remains positive and steadily increases up to 28.5 MHz, after which it starts to decrease, until it becomes 0 ohm at 27 MHz, and negative below that frequency. At 27 MHz impedance is 9 + j0 ohm (hence it is the resonant point).

I knew that the resonant point does not precisely coincide with the minimum SWR point, but I would not have suspected such a big difference (2 MHz shift at 29 MHz!).

Any comment?

that is not surprising for an antenna that has a very low or very high
impedance at the resonant point. The SWR depends on the magnitude of the
impedances not the angle, so you could have a minimum SWR with a big
reactance and small real component.

There's a thread over on eHam.net dealing with this same subject.
Many complex antennas exhibit this effect to a certain extent. The
reason is obvious. Our SWR meters are calibrated for 50 ohms and
an antenna may be resonant with a e.g. 9+j0 ohm feedpoint impedance.

That's a 50 ohm SWR of 5.6:1 where almost 1/2 of the RF is rejected
at the antenna when 50 ohm coax is being used. If the 50 ohm SWR
drops below 5.6:1 somewhere else it necessarily must exhibit a
higher resistance and reactance than exists at the 9 ohm antenna
feedpoint.

Moral: There is nothing magic about 50 ohms. If you were using
a transmission line with a Z0 of 9 ohms with a 9 ohm SWR meter,
you wouldn't notice anything worth reporting.

That's not true. For example, impedances of 50 + j0, 35.36 + j35.36, and 0 + j50 ohms all have the same magnitude (50 ohms), but a 50 ohm cable connected to loads of those impedances will have SWRs of 1, 2.41, and infinity respectively.

Correct formulas for calculating SWR can be found in the ARRL Antenna Book, the ARRL Handbook, or any respectable transmission line text. Incorrect ones can, I'm sure, be found on the Web and elsewhere.

Check the Alt Z0 option button at the upper left of the SWR display.
What happens to the minimum SWR frequency? Then change the Alt SWR Z0
value in the main window to some other value, say 300 ohm. What effect
does that have?

Interesting, isn't it?

VSWR is not defined in terms of the conditions for resonance.

The characteristic of some kinds of antennas (including half wave dipoles and quarter wave monopoles over ground) with resonant impedance near 50 ohms is that the R component of feedpoint Z varies slowly with frequency around resonance (X=0) and X varies relatively quickly with frequency around resonance. Because of this, in the region of resonance (X=0), X tends to dominate VSWR(50) and the VSWR(50) minimum will be quite close to where X=0.

Whilst many folk equipped with MFJ259Bs or the like, and with less understanding, tune such an antenna for X=0, it is likely that the higher priority for system efficiency is to tune for VSWR minimum. Worse, they often do it at the source end of some length of transmission line.

I canvass the issues in the article "In pursuit of dipole resonance with an MFJ259B" at http://vk1od.net/blog/?p=680 , you may find it interesting.

Actually, there is something 'magic' about 50 ohms. An air-dielectric co-axial cable has minimum loss per metre when its characteristic impedance is 76.7 ohms and the relative permittivity of polythene is 2.26 so a polythene-dielectric co-axial cable has lowest loss when its characteristic impedance is 76.7/SQRT(2.26) = 51 ohms, which is most often rounded down to 50. This is on the basis that the conductor loss greatly exceeds the dielectric loss, which is true over most of the frequency range for which solid polythene dielectric is appropriate.

Maximum power handling, for a polythene-dielectric cable, occurs at a much lower impedance: 30/SQRT(2.26) = 20 ohms.

>
> Roy Lewallen

Yes, changing the Alt Z0 makes a dramatic effect, and setting it to 9 ohm obviously causes the minimum SWR point to shift from 29 to to 27 MHz (reaching 1:1).

Interesting to note that, using a 75-ohm cable, one can get a perfect match to the simulated spiderbeam antenna in two possible ways:

- either cancelling the antenna reactance using a -32 ohm series-capacitor. One then gets a (nearly) perfect match at 29 MHz, where antenna impedance is 76 + j32 ohm

- or using a 9:75-ratio transformer. One then gets a perfect match at 27 MHz (where impedance is 9 + j0 ohm)

Another interesting observation is that, at 29 MHz (i.e. where the antenna impedance is 76 + j32 ohm and the SWR on a 75-ohm cable shows the minimum value of 1.95) one can find a cable length at which the impedance appears to be purely resistive and equal to 1.95*75 = 146 ohm (or 75/1.95 = 38.5 ohm). This fact is deceiving as, seeing a purely resistive impedance, one could be led to concluding that the real antenna resonant frequency is 29 MHz, whilst in reality it resonates at 27 MHz (although knowing what is the real antenna resonant frequency may not be so important).

I raised the above arguments just as a confirmation of the fact that understanding what to do before attempting to adjust antennas is not that easy.

> Actually, there is something 'magic' about 50 ohms. An air-dielectric
> co-axial cable has minimum loss per metre when its characteristic impedance is
> 76.7 ohms

I presume that the 76.7-0hm figure comes from a trade-off beween RF current and conductor resistance. In other words, increasing the impedance value, the RF current would become lower (for a given RF power), but the inner conductor resistance would become higher because of the lower diameter needed to obtain the higher impedance value (for a given outer diameter cable). And viceversa.

> and the relative permittivity of polythene is 2.26 so a polythene-dielectric
> co-axial cable has lowest loss when its characteristic impedance is
> 76.7/SQRT(2.26) = 51 ohms, which is most often rounded down to 50.

Under the assumption that dielectric loss is negligible, a permittivity 2.26 time higher than that of air results in a lower inner conductor diameter, for a given outer diameter cable and a given impedance. Probably, lowering impedance from 75 to about 50 ohm, the loss advantage one experiences thanks to the higher inner conductor diameter needed for the lower impedance value is higher than the loss disadvantage caused by the higher RF current (for a given RF power).

> Maximum power handling, for a polythene-dielectric cable, occurs at a much
> lower impedance: 30/SQRT(2.26) = 20 ohms.

I do not succeed to understand that statement. Maximum power handling is bound to maximum temperature which is in turn bound to dissipated power. If 50 ohm is the impedance at which minimum loss occurs (for a given RF power), why lowering impedance to 20 ohm should result in a loss reduction. In the equation 30/SQRT(2.26) = 20 ohms, which is meaning of the figure 30?

I wonder whether you could indicate us a reference where all those trade-offs are mathematically discussed.

Thanks Jeff, that reference does help but it gets a bit confused over matters of relative permittivity, Er.

Some time ago (2005), in my work, I derived the whole lot from almost first principles. It turns out that the series conductor loss (as opposed to the shunt dielectric loss) is proportional to (1+p)/ln(p), where p is the ratio of the inside diameter of the outer conductor (D) to the outside diameter of the inner conductor, and to SQRT(Er). The minimum value of this loss is found by differentiating the function of p with respect to p and that's what gives the 76.7 ohms value for Er = 1 (it also involves a constant for copper conductors, the root frequency and 1/D). The result scales with SQRT(Er) for polythene.

I should have stated the _peak_ power handling because the 30 ohms (air) value results from combination of the expression for the electric field strength and the expression for the characteristic impedance (along the lines of P = V^2/R). Minimising the field strength gives the greatest resistance to dielectric breakdown, but a different value of p results when the impedance is taken into account at the same time. Again, the result scales with SQRT(Er).

The application for all this was analogue to digital terrestrial television switch over - the digital signals have much greater peak-to-mean ratios than the analogue ones, so flashover in air-spaced feeders is a potential power limitation.

No one with a basic understanding of transmission lines would think that the frequency at which resonance occurs (X = 0) at the input end is the same frequency at which the load is resonant, except for two special cases -- if the line Z0 equals the load resistance at the load's resonant frequency, or the line is an integral number of quarter wavelengths long at the load's resonant frequency. And, as you imply, the resonant frequency of the antenna itself has no significance. Transmission lines have been used for over a hundred years for impedance matching, transforming a load of complex impedance into a purely resistive impedance of a desired value.

> I raised the above arguments just as a confirmation of the fact that
> understanding what to do before attempting to adjust antennas is not
> that easy.

The way to begin is to gain a basic understanding of how transmission lines transform impedances. The ARRL Antenna Book is a good resource. If a person's knowledge is limited to only vague understandings of SWR and resonance, antennas and transmission lines will be a constant source of mysterious and unexpected results.

Yes, and this is why foamed dielectric cable has lower loss than solid dielectric cable. Not because of lower dielectric loss (at least below a few GHz), but because it has a larger center conductor for the same impedance and outside diameter.

> that easy.

Well, it was easier until people that don't understand the fundamentals of transmission lines got access to instruments that measure R and X, and used their new found capability to prop up the "resonant antennas work better" myth.

For many common ham antenna *systems* (eg a length coax feed to a centre fed, approximately half wave dipole using an effective balun), system efficiency is best when transmission line losses are least, and minimising line VSWR is a good first cut for best efficiency. Having done that, an ATU at the tx to transform the load to that required by the tx so that it can deliver its rated power with specification linearity may be needed.

If you drill down on the resonance myth, its greatest validity is that for some types of antenna systems (including the one described above), resonance delivers a low VSWR, approximately the minimum VSWR, and in those systems leads to approximately lowest line loss, resulting in best efficiency. Nothing to do with the 'technical' explanation that I heard the other day that a "resonance antenna fairly sucks the energy out of the transmitter". It is a course a fallacy that resonant antennas naturally "work better", or that resonance is a necessary condition for high efficiency.

It is pointed out to me from time to time that the article that I referred you to earlier is way above the head of the average MFJ259B user, but it is my contention that you cannot realise much of the potential of the MFJ259B or the like without understanding transmission lines. VNAs are the new wave of instruments with potential exceeding typical user's desire for understanding.

2188. high power 4:1 balun

Newsgroup: rec.radio.amateur.antenna
Date: 2009-09-20 21:40:39 UTC
From: Ralph Mowery <rmowery28146@earthlink.net>
Message-ID: <DsqdnVqKm4xEPSvXnZ2dnUVZ_uGdnZ2d@earthlink.com>
Source record: 13050

Does anyone make a 4:1 balun that I can use for an off center fed antenna that will take the legal limit of power ?

I did find one that is around $ 80 to $ 100 that is suspose to handle it. I hate to pay that much for a ring of 'iron' and a few feet of wire wound on it and it will not work.

I have up a home made version of the Carolina Windom. Bought a balun rated for 1.5 kw. I only run around 1200 watts out of a Drake L4B amp. That balun will heat up and quit working (swr goes way up from about 1.7:1 at the frequency I use most) if I run more than about 500 to 600 watts SSB to the antenna for any length of time. The antenna is fed with a good grade of rg8 and about 20 feet from the antenna is a current balun (the one with the beads over the coax). It will heat up some but when I take it out of the line, the 4:1 balun still heats up . The 1:1 bead choke does not heat up to any big ammount when I put it on a dummy load and put 1200 watts to it.

I had a low power balun up with the same antenna and running 100 watts the antenna seemed to work fine.

If it was not for the wide bandwidth and good results I have been getting , I would just run an 80 meter dipole and no balun. Also want an antenna for 40 meters.
Have the usaul triband for 10,15,20.

Is it too hard to quantify the power limit? It is jurisdiction dependent.

Talking in numbers is the beginning of understanding the problem. (A
loose paraphrasing of Lord Kelvin).

The Carolina Windom seems to use a 4:1 voltage balun and a 1:1 current
balun closer to the tx. (I say seems because IIRC it is a proprietary
design.)

The loss in the voltage balun can be expected to be severe when the load
impedance is very high due to the resultant high flux level in the core.

Whilst commercial producers commonly state power limits, and often
extravagantly, few manufacturers give you loss characteristics,
especially for impedances a long way from nominal.

For an experiment, I measured the "heavy duty" 4:1 Ruthroff balun in a
popular 300W rated ATU with a VNA, and calculated efficiency of the balun
feeding a G5RV on five bands. Efficiency of the balun varied from 66% to
almost 100%. (Notes at http://vk1od.net/blog/?p=568 .)

It is my guess that the balun could safely dissipate say 10W continuous.
Then at 66% efficiency, it would only safely accept 30W continuous input.
Fortunately, the peak to average ratio of SSB is something like 30:1, so
it would probably handle 1000W PEP SSB telephony ok.

Rule no 1: Balun manufacturers often supply little information.

Rule no 2: Information that is supplied is of little use in establishing
behaviour on extreme loads.

> amp. That balun will heat up and quit working (swr goes way up from
> about 1.7:1 at the frequency I use most) if I run more than about 500
> to 600 watts SSB to the antenna for any length of time. The antenna

Using my peak to average ratio, you are talking about an average power of perhaps 20W.

You have probably reached the Curie point of the core, and it can be quite low depending on the mix.

It is not unusual that 4:1 voltage baluns that have adequate performance on a 200 ohm load have efficiency less than 50% on extreme loads such as might be experienced with the CW.

> is fed with a good grade of rg8 and about 20 feet from the antenna is

The heating of a choke is due to flux cause by common mode current, and some copper loss. Did your test configuration have zero common mode current?

Though some show mathematical derivation for the magnitude of common mode current based on Zo alone (which leads to Rule 500), it is my contention that approach is not valid in an antenna application, and common mode current may be much higher or lower than indicated by that method.

Don't overlook that a lossy balun leads to lower VSWR, and that is often erroneously interpreted as an indicator of "good results".

Source record: 12903

My post below is not exactly on target for the thread, but I believe useful. It's Sec 11.3 from Chapter 11 of Reflections, the whole of which is available on my web page at www. w2du.com.
The title of the Sec is "A Reader Self-test and Minimum-SWR Resistance."

Sec 11.3 A Reader Self-Test and Minimum-SWR Resistance

" Everyone knows that when a 50-ohm transmission line is terminated with a pure resistance of 50 ohms, the magnitude of the reflection coefficient,, rho , is 0, and the SWR is 1:1. Right? Of course! With that in mind, here is a little exercise to test your intuitive skill. If we insert a reactance of 50 ohm in series with the 50-ohm resistance, the load becomes Z = 50 + j50. The SWR will be 2.618:1. Now for the question. With this 50-ohm reactance in the load, is the SWR already at its minimum value with the 50-ohm resistance, or will some other value of resistance in the load reduce the SWR below 2.618:1? You say the SWR is already the lowest with the 50-ohm resistance, because, after all, the line impedance, ZC, is 50 ohms? Sorry, wrong. With reactance in the load, the minimum SWR always occurs when the resistance component of the load is greater than ZC. In fact, the more the reactance, the higher the resistance required for to obtain minimum SWR. For any specific value of reactance in the load there is one specific value of resistance that produces the lowest SWR. I call this resistance the "minimum-SWR resistance." Finding the value of this resistance is easy. First you normalize the reactance, X, by dividing it by the line impedance, ZC. The normalized value of X is represented by the lower case x. Thus x = XC / ZC. Then we solve for the normalized value of resistance r, from Eq 5-1, which is repeated here.

r = sqrt (x^2 - 1) Eq 5-1

Let's try it on the example above. The normalized value of 50 ohms of reactance X, is x = 1. Substituting in Eq 5-1, r = sqrt 2 = 1.414. So the true value of the minimum-SWR resistance is 1.414 x 50 = 70.7ohms. While the 50-ohm resistance yields a 2.618:1 SWR, the 70.7-ohm resistance in series with the 50-ohm reactance yields an SWR of 2.414:1. Not a great deal smaller, but still smaller than with the 50-ohm resistance.

So let's try a more dramatic example, this time with a 100-ohm reactance, which has a normalized value x = 2.0. With a 50-ohm resistance, the SWR is now 5.828:1. However, with the normalized minimum-SWR resistance, r = sqrt 5 = 2.236. Multiplying by 50, we get R = 111.8 ohms. With this larger resistance in series with the 100-ohm

reactance, the SWR is reduced from 5.828:1 to 4.236:1. The results of this exercise didn't turn out quite the way you expected, did it?"

For further proof of this concept I suggest reviewing the remainder of this Sec using the Smith Chart, available from my web page.

Well, it for a distortionless 50 ohm line.

Continuing on the distortionless example, if you visualise this on a Smith chart, for any constant X and R independently variable, the value of R for minimum VSWR will be such that the tangent to the reactance circle is also a tangent to the VSWR circle at that point (R,X), and R for minimum VSWR will always be greater than Ro for Xl<>0.

However, Zo for practical cables is not real, not quite.

It isn't the amateurs so much as the advertising. Marketing departments
highlight the foam dielectric because it's more obvious, and pretty soon
even the manufacturers are believing their own publicity.

As for the 50-ohm impedance, the reasons why it became an industry
standard are interesting but purely historical. The reason for using it
now is almost exclusively because it *is* an industry standard.

"electromagnetic waves" are paper waves. Radio waves are real waves. Now we
must not know what the waves are like. Now we should estabilish from which
part of the radiator radiate the radio waves.
Do you agree with Richard Harisson:
"At the open circuited ends of a resonant antenna there is almost double
the forward voltage but zero total current due to cancellation of the
dorward and reflected currents at the open circuit. At the open circuit
in the wire, all the energy in the wave is transferred to the electric
field."

All necessary resarch are done by radio people. You all know how antennas work. Monopole and dipole means the electric pole because no magnetic poles. You only do not realize that EM waves can start from the ELECRIC field. The electric field is radiated from the ends where is high voltage and no current.

No, Szczepan, it is you that does not realize that voltage, alone, cannot produce an electromagnetic field.

Only the change in current and charge flowing along a conductor, over time, produces far-field EM radiation. That radiation includes both the magnetic and electric fields, at right angles to each other and to the direction of travel.

It is untrue that one part of a conductor or antenna radiates the magnetic field, and another part radiates the electric field, no matter the claims of the proponents of the E-H antenna (which have not been demonstrated).

The fact that the ends of a dipole, and the top of a monopole have very little net current flowing means that those locations cannot contribute very much to the EM radiation from those antennas.

You really should form your opinions from research in modern textbooks on antennas, rather than using Wikipedia and inapplicable analogies to sound waves. At a minimum you could recognize the quotes from them on this subject that already have been posted here.

> S*

What Richard wrote is correct, if written in a slightly provocative manner (deliberately?). But he wasn't stating that the electric field 'At the open-circuited ends of a resonant antenna' passes energy into a radiated radio wave. The energy that makes it that far (i.e. isn't radiated on account of current in the element) is stored temporarily in an 'electrostatic' field which is one of several 'reactive' or 'induction' field components that surround a dipole antenna and decay with distance much faster than the radiation field components (i.e. those that make up a radio wave). As I've noted before, the term 'electrostatic' should not be interpreted literally as an unchanging field - it is used to differentiate between the reactive components and the radiation components of electric field - if this offends you, just call it a 'reactive' component of electric field. This stored energy is passed back into the antenna during the following RF quarter cycle.

And guess what ... one of the reactive field components is longitudinal!

... but it isn't part of a radio wave - both parts of a radio wave, the magnetic field and the attendant electric field, are directed transverse to the direction of propagation, but now I'm repeating myself from a week or more ago. Power cannot be abstracted from the reactive fields, including the longitudinal one; they affect the imaginary part of the terminal impedance of the antenna.

Of course, I expect you will contradict all this but I still recommend that you read a proper account of the fields around a dipole rather than making

up your own version. Since you appear to have a phobia of libraries, you could buy a second-hand copy of Kraus, Antennas for only $15 online: http://www.abebooks.com/servlet/SearchResults?an=Kraus&sts=t&tn=Antennas&x=55&y=10 and there are many, many other sources.

Failing that, you could always search the web for a bootleg copy, or one of the MIT Radiation Laboratory series of books. I don't condone bootlegging but someone in another newsgroup recently gave a link to a collection of illegal copies and, in the hope of ending these ridiculous arguments, I'll pass on what he wrote: http://cer.ucsd.edu/~james/notes/MIT%20OpenCourseWare/MIT%20Radiation%20Lab/

See my post earlier in this thread. You are misinterpreting what Richard Harrison wrote to suit your own, incorrect, made-up version of how antennas work.

Please think on this, Szczepan Bia�ek: the likelihood that your personal version of the physics is correct is vanishingly small - when it conflicts with the version everyone else (except perhaps Art Unwin) appears to understand from their education, which is derived from the basis for antennas that have been in use for more than 100 years.

These guys are not helping you! What they are doing is using you for
cannon fodder.
Try looking at things my way. You know that when a time varying
current is applied to a radiator that it also supports a reacting
current with spin, known as as an Eddy current
You also know that the current applied produces a electrical field and
a magnetic field that interchange energy between each other in the
form of a tank circuit.
Now look at the sequence of actions.We do know that the Eddy current
produces a lifting force and a spin force and we also know that there
is a electro static field surrounding the radiator. First we must
recognise that particles encapsulate the whole radiator but can be
individually lifted from the radiator with spin applied a short
distance. At this point it enters the electrostatic field around the
radiator where at the same time the generated magnetic field is
intersecting the electrostatic field. The moment that the lifted
particle enters the electro static field mix it is subjected to a
accelarating force exactly the same way as a electron in a CRT is
impacted upon. If you refer to the actions within a electron tube you
will note that the electrostatic field offsets the direction of the
accellerated particle into an exiting parabolic direction. The
combined fields will only accelerate the particle while it is within
the electrostatic field proper, after which it has a straight line
projection with spin. The time that it is within the electrostatic
field is the total accelerating time ie Newtons law 1/2 ft sqd.
The acceleration imparted to the particle happens to be the speed of
light which implies that this particle is able to emit light. If you
have difficulty then read up on the CRT.

As a point of interest the Eddy current itself must be balanced by an equal and opposite force per Newton and if we look at it in boundary terms we see that the opposing force is the combination of Gravity and the rotation of the Earth. What this shows is that the particle has spin and accelleration where the vector associated with Gravity is now neutralized such that it retains its straight line action with spin as it traverses the boundaries of the Earth Another thing of importance is that Newtons laws are based on the condition of mass where the particle becomes an excellent fit as opposed to a field or a wave.
Back to the radiator itself. If it is a full wave length then it is a closed circuit of the tank circuit form. If a radiator is less than a wave length then yes, charges will form at the end of a radiator but is hampered from further movement by the opposing impedance of the environment. The charges will still leak but with out a spinning action it will remain in the near field. Ofcourse changing the environment will give an instantaneus charge in a spark form because as an open circuit it always searches for the closed circuit function.

That's hilarious!

We're not using Mr. Bialek as 'cannon fodder' - he is presenting himself as cannon fodder voluntarily and he has the power to stop this happening. The same applies to you. But the concept of him looking at things your way is akin to a nun on a clowns head.

Eddy currents are not named after someone called Eddy and the speed of light is a speed so it cannot be an amount of acceleration. Any takers for the other faux pas?

Chris

I can imagine an Uncle Eddy, but for equal and opposite - Auntie Eddy?

If an eddy circulates in one direction (maintaining the hydrological
metaphor of Stefan's) Auntie Eddy must run opposite. So now the Art
of Antenna Bris finds itself in a backwash.

2210. Re: high power 4:1 balun

Newsgroup: rec.radio.amateur.antenna
Date: 2009-09-21 21:28:40 UTC
From: Karl Beckman <Karl.Beckman@motorola.com>
Message-ID: <h98r6b$ab0$1@engnntp2.cig.mot.com>
Source record: 12944

First thing to remember is a really radical thought: The power rating of a voltage balun has to be decreased by the highest SWR factor existing on the line. That is, a 2 kW rated (at 1:1) balun is only good for 1 kW at 2:1 VSWR or 200 watts if your wattmeter shows a 10:1 VSWR looking at the antenna. The reason is that the current (heating) losses in the windings go up as the square of the maximum current - remember hearing about "I squared R". A 4:1 VSWR means the current max value is twice the minimum, therefore you'll be heating up the core four times as much as if you had a 1:! VSWR on the line. It doesn't matter whether the line is unbalanced coaxial or balanced open wire.

In your case the ratio of rated power divided by working power is 1.25, so the maximum VSWR tolerable before you exceed the dissipation rating of the balun is only 1.25. Or working the other direction, to always stay cool you need to find a balun rated for (1200) x (VSWRmax) watts.

The input reactance of the Windom changes as you change the driving frequency (and band), therefore the VSWR on the feedline does also. The balun may stay reasonably cool on a few frequencies, but will be flaming hot on most others.

Chris you are being stupid as well as acting as a fool.
Acceleration of the particle only occurs while within the
electrostatic field. When it exits it has the speed of light because
it has emmerged from the intersecting two fields.and thus from the
accellerating forces. I remind you of Newtons law of ut + 1/2 ft sqd
The first expression is for the speed attained on entering the

accelerating field and the other half is for the length of the
accelerating electrostatic field. On leaving the two fields it looses
the applied accelerating force where it has arrived at a particular
speed.Maybe you should look up the workings of a CRT using Newtons
laws instead of shooting from the hip.
It was at a different time that the speed of light was measured where
it was found to equal the sppeed emerging from two intersecting fields.

we know what they are like, you just have to understand the mathematics.
and yes, richard's statements are true, but a bit too restrictive, it
doesn't HAVE to be resonant. Voltage doubles and current=0 at the end of
any wire fed with a time varying current, it doesn't even have to be a sine
wave... note the effect of sending square waves from a time domain
reflectometer down an open circuited wire.

Chris you are being stupid as well as acting as a fool.
Acceleration of the particle only occurs while within the
electrostatic field. When it exits it has the speed of light because
it has emmerged from the intersecting two fields.and thus from the
accellerating forces. I remind you of Newtons law of ut + 1/2 ft sqd
The first expression is for the speed attained on entering the
accelerating field and the other half is for the length of the
accelerating electrostatic field. On leaving the two fields it looses
the applied accelerating force where it has arrived at a particular
speed.Maybe you should look up the workings of a CRT using Newtons
laws instead of shooting from the hip.
It was at a different time that the speed of light was measured where
it was found to equal the sppeed emerging from two intersecting fields.

* Actually, I'm well aware of the principle involved in accelerating
electrons in an electron gun as used in CRTs, klystrons, TWTs, and so on, by
subjecting an electron cloud to a potential difference using an anode with a
hole in it (!), but that's different from what happens in an antenna.

The acceleration of charge in an antenna results almost entirely from the
applied potential difference at its terminals. The radiated fields result
from the alternating current effectively passing through the radiation
resistance, and all the other, reactive, fields have no direct effect on the
radiation resistance, or the component of the current that passes through it
in phase with the voltage that is developed across it, which together, of
course, represent the radiated power. The reactive fields affect the
terminal impedance and a large imaginary part can upset the device trying to
send power into the antenna, but that is more of a system issue. The
alternating current that passes through the radiation resistance is composed
of charge that moves in time with each RF cycle, accelerating and
decelerating accordingly. The electrostatic field developed between the
ends of a half-wave dipole reaches its maximum value a quarter of a cycle
later than the voltage at the drive point so any effect it has on the charge
in the antenna elements during each cycle must be reactive, and it doesn't
affect the radiation resistance or the radiated wave.

But all this can be looked up from any one of the respected books on
antennas. Kraus, and others, gives expressions for the different field
components and the theory all hangs together quite readily using Maxwell's

equations without modification.

I don't care if you think me stupid, and I'll continue to try to avoid name calling of individuals, although I may criticise what they write especially if it appears ignorant of proper science yet attempts to re-write established theory, and therefore appears arrogant.

Chris

No it does not appear in Kraus book. He never followed Maxwells laws
with respect to equilibrium. To do that you must think in terms of
wavelength. After all with respect to science all revolve around
boundary laws of the Universe and you blindly ignore that fact.
Now back to radiation which applies spin to a p. Nowarticle where as
with a crt no spin is applied as it is heat that separates the resting
particle Now earlier you refered to a electrostatic field that
according to what you stated did not have a border and surely you know
that just can't be unless it is in equilibrium which requires a closed
circuit.
For this to come to fruition you go back to the boundary laws where
the arbitrary border is one that is closed i.e. in equilibrium. Now
cast your mind back to the Gauss extension where radiators and
particles lie in a closed static field. Now you should see that
equilibrium must reign for a closed static field. Now you blithely
mentioned an electrostatic field with nary a mention as to how it is
formed and how it fits into the whole picture.
Why? Because the books do not provide an unbroken trail that fully
describes radiation
(books admit that) as I have done where everything dove tails into
the existing laws of the Universe. And then I gave you a bonus with
respect to the weak field that Einstein searched for in vain. Einstein
looked at the package presented by the Big Bag but omitted to keep
that which it was wrapped into. That was the arbitrary boundary around
which were forces or vectors that were equal and opposite when a
smallest of smallest of particles edged out towards the border. Yes it
was of a weak force but for all of that it broke the equilibrium
boundary as the forces at that point was not now equal. The breakage
was one where the opposing forces were offset to each other thus
providing a torque force that provided spin. Now we come to our own
Earth encased in a arbitrary border and outside the border we have the
same conditions of equilibrium that must equal the forces of the Big
Bang which means the outside has two vectors, gravity vector which is
straight and a vector denoting spin i.e. rotation of the Earth. On the
other side of the border you again have two vectors a straight vector
and that curly one you don't like me to call eddy current.

Yup. Everything falls together nicely thank you, when you study
radiation from first principles instead of binding yourself to books
that readily admit to not understanding the radiation process. Now
this is not being arrogant when one has applied all principles but I
do think it is arrogant of you and others to asasinate the character
of "S" purely because of his english and spelling and not to help one
that wants to learn.
Just think about it all. I have shown how a particle moves in space in
a straight line trajectory such that the particle maintains a straight
line without the parabolic force of gravity driving it down to the
Earth. Go back to your books and show just how the electrostatic field
came about and what was the borders that it was contained in
Art
via applied spin and where gravity

Nice job on the name calling, dingbat.

So, which charged particle are you proposing is being accelerated here?
There are none that have no mass, which would mean that no particle
capable of being accelerated by an electrostatic field could exit at
"the speed of light because it has emmerged from the intersecting two
fields".

Have you now discovered a new particle which has charge and no mass?

You are talking garbage Tom in a attempt to sound educated.
When you introduce Newtons laws you are standing on the existence of
mass.
It was a particle with mass that broke the equilibrium of the Sun
which starts the whole cycle.
This mass is debris from the burning and release of energy from the
sun which ebbs and flows according to the 11 year sun spot cycle. It
is acknowledged that particles from the Universe are in the billions
per cubic meter in the Earths system and all these particles have
mass. The idea that neutrinos, a particle from the Sun had no mass was
dispelled years ago, so the Laws of Newton remains in place. This very
same action is shown with respect to a CRT where the particle which in
that case does not have spin. You will see that the particle is
accelerated within the borders of the electrostatic field which is
also intersected by a mgnetic field such that its path is parabolic
within the confines of the electrostatic field which becomes a
straight line travel without acelleration as it leaves the confines of
the electrostatic field. It is all quite simple Tom but you continue
to implant erronius data into the description as a basis to supply
insults.

You could go to college and learn all this but here goes.
Planck did a treatise on heat radiation where he stated that heat
radiation
is enabled by two independent functions. First was by conduction and
the second by a ray.
He went on to enlarge on the notion of a ray when is studies moved on
to radio and light radiation. He often consulted with Einstein and was
well aware of his efforts to find the weak force and where he gave up
on that and started a new science where he came up with mc sqd,. With
the abandoned search of Einstein Planck settled hard on the idea that
light was a radiated beam or wave of sorts and it was natural of him
to see radiation of heat in a similar manner i.e a wave or ray in a
similar way that light was thought of.
In fact his work moved later to the nature of light and radio
radiation where the theme of a ray or wave was retained. If Einstein
had included the wrappings of the Big Bang in his studies particles
would have retained the high ground for both him and Planck.
as well as this group together with science which has been misled to
this very day.
Thus Planck started on the wrong track with respect to heat radiation
and all of his other studies. Now he may have known what the speed of
light was but he would see it as a ray of light the same way as a ray
of heat. It was later found independently that a particle at the exit
from the combined field intersection was the speed of light which now
can be seen as the cause of light in connection with particle speed
i.e an effect and not a cause.
Since we note that wavelengths can denote a change of color the
connection of wavelength, spin ,deccelleration or what ever, directly
relates to the emmission of light.
So to answer your question the cause of this particular speed is the
interaction of two intesecting fields on a particle of mass. This same

particle is the same particle that emits light which cannot exceed the speed attained in the combined fields since there is no applied accellerating force applied to that same particle ,only retardation. And this is the same particle that sits on a diamagnetic material that is removed from a heated anode without spin but with an increase in potential energy. Without spin this same particle deccellerates before impacting on a luminescent glass surface of a CRT.

Give references. This is the key to your argument, in case you can't
figure that out. It also breaks all current laws of physics.

All that time I took to educate you was all for nothing
On top of that you accused me of breaking the laws of physics which
can only be the laws as you under stand them which is different to the
rest of the World. I also note that you have insulted another person
of the group calling him dirt.
Really you need to read a book of the World as we know it where the
magnetic fields of the Earth become inert to change and the forces of
the standard model reverse to the point of beginnings. When this
reverse begins the dead will rise and it will be heaven
as we then grow younger. Ofcourse those who decided to stay on the
side of the Red sea
will not rejoin the others that stayed on the right path which suggest
that the Middle East will be destroyed as the majority of the tribe
descendants lives there. Ofcourse if you have lived a life where you
insulted all you certainly will not be "one of the meek" that gets
blessed. Yup, read a different book next time and check out the laws
that we all have violated.

It apply to 1/2WL dipole. But what radiate in 0.05WL dipole? There the
"maximum radiation " is in the transmission line (1/4WL from the end). The
feed point is also in the transmissing line.
"R. Clark wrote : "[* What is this proportional and

Rather no. Richard do not write about a feed point.

Look at this: ""At the open circuited ends of a resonant antenna there is
almost double the forward voltage".
"Almost double voltage" is like the pressure in the Kundt's tube.

For me it is important that at the end the voltage is doubled: "At the open
circuited ends
of a resonant antenna there is almost double the forward voltage".

I am colecting such arguments from radio people posts.

I understand. Without that it was be impossible to know that Maxwell
proposed the displacement current to save the incompressible electric fluid.
In Maxwell times AC current was known. To pass the incompressible fluid
through a capacitor the displacement current is necessary. I prefere the
compressible electrons. They compress in the plates and nothing flow between
them. The polarization is not the macro flow.

>No, Szczepan, it is you that does not realize that voltage, alone,
cannot produce an

Let us assume that electromagnetic field is a proposition by Maxwell.
The electric field is more realistic.

>Only the change in current and charge flowing along a conductor, over
time, produces far-field EM radiation. That radiation includes both
the magnetic and electric fields, at right angles to each other and to
the direction of travel.

>It is untrue that one part of a conductor or antenna radiates the
magnetic field, and another part radiates the electric field, no
matter the claims of the proponents of the E-H antenna (which have not
been demonstrated).

But it is experimentally proved. Stationary charge - electric field, Moving
charge - magnetic field.
Probably the both fields are the same. Only instruments are different.

>The fact that the ends of a dipole, and the top of a monopole have
very little net current flowing means that those locations cannot
contribute very much to the EM radiation from those antennas.

But there are the doubled voltage. Very strong pulses must appear in space.

>You really should form your opinions from research in modern textbooks
on antennas, rather than using Wikipedia and inapplicable analogies to
sound waves. At a minimum you could recognize the quotes from them on
this subject that already have been posted here.

Up to now the acoustic analogy is fully applicable.

S*
>These guys are not helping you! What they are doing is using you for
cannon fodder.

Day after day they state the new for me aguments that the acoustic analogy
is the winner.

>Try looking at things my way. You know that when a time varying
current is applied to a radiator that it also supports a reacting
current with spin, known as as an Eddy current
You also know that the current applied produces a electrical field and
a magnetic field that interchange energy between each other in the
form of a tank circuit.

You go into details. Now is not time for that. Now we should work out the
consensus on which part of the radiator radiate the radio waves.

>Now look at the sequence of actions.We do know that the Eddy current
produces a lifting force and a spin force and we also know that there
is a electro static field surrounding the radiator. First we must
recognise that particles encapsulate the whole radiator but can be
individually lifted from the radiator with spin applied a short
distance. At this point it enters the electrostatic field around the
radiator where at the same time the generated magnetic field is
intersecting the electrostatic field. The moment that the lifted

particle enters the electro static field mix it is subjected to a accelarating force exactly the same way as a electron in a CRT is impacted upon. If you refer to the actions within a electron tube you will note that the electrostatic field offsets the direction of the accellerated particle into an exiting parabolic direction. The combined fields will only accelerate the particle while it is within the electrostatic field proper, after which it has a straight line projection with spin. The time that it is within the electrostatic field is the total accelerating time ie Newtons law 1/2 ft sqd.
The acceleration imparted to the particle happens to be the speed of light which implies that this particle is able to emit light. If you have difficulty then read up on the CRT.
As a point of interest the Eddy current itself must be balanced by an equal and opposite force per Newton and if we look at it in boundary terms we see that the opposing force is the combination of Gravity and the rotation of the Earth. What this shows is that the particle has spin and accelleration where the vector associated with Gravity is now neutralized such that it retains its straight line action with spin as it traverses the boundaries of the Earth Another thing of importance is that Newtons laws are based on the condition of mass where the particle becomes an excellent fit as opposed to a field or a wave.
> Back to the radiator itself. If it is a full wave length then it is a closed circuit of the tank circuit form. If a radiator is less than a wave length then yes, charges will form at the end of a radiator but is hampered from further movement by the opposing impedance of the environment. The charges will still leak but with out a spinning action it will remain in the near field. Ofcourse changing the environment will give an instantaneus charge in a spark form because as an open circuit it always searches for the closed circuit function.

It will not be easy to work out here all details.

> Yes. But antennas are in resonance.

That is rarely true.

A naturally resonant antenna has zero reactance at its feedpoint. But that is not a requirement for it to produce EM radiation efficiently from all of the r-f current flowing on it.

The monopoles used by MW broadcast stations vary from 60 to 225 electrical degrees in height. Only a few of those heights are naturally resonant.

Yet they all radiate nearly 100% of the applied power, because any antenna reactance is offset by an impedance matching network at the feedpoint.

Hi All,

A bit trivial but very common problem...
I got a free 203BA i had to remove from a tower. It has been there for years.
All parts are OK except that i can't dismantle some elements. Certain tube junctions are corroded despite some tape protection, and the elements are like soldered.

Is there a safe way to remove the aluminium oxide so i can disassemble the elements for transportation ?

I've been told that letting petroleum seep between the elements would help. But that can take days or ... weeks...

I'm sure, you all had this problem one day and that someone found a "good" solution.

Thanks for any comments,
73, Patrick TK5EP

Szczepan Białˇek wrote:
> For me it is important that at the end the voltage is doubled: "At the
> open circuited ends
> of a resonant antenna there is almost double the forward voltage".

The same thing happens with an open-circuit stub yet it
radiates a negligible amount. The only place where an
antenna radiates more than a negligible amount is where
the forward and reverse currents are unbalanced.

At the ends of a 1/2WL dipole, the forward and reverse
currents are perfectly balanced, i.e. they are 100%
transmission line currents which are known not to
radiate.

At the 1/2WL dipole feedpoint, the forward and reverse
currents are most unbalanced, i.e. since they are in
phase at the feedpoint, they can be considered to be
100% antenna currents.

This is just one more example of the illogic of
forcing forward and reflected waves into a mashed
potatoes theory of energy. The underlying laws of
physics are lost in the process.

Not if one understands the physics of radiation.

> But it is experimentally proved. Stationary charge - electric field,
> Moving charge - magnetic field.

Untrue, and I challenge you to cite any credible experimental data
that you think proves your belief.

Far-field EM radiation is produced only by the current flow on the
antenna, and that radiation contains BOTH the electric and the
magnetic fields.

You may have missed the accurate description posted by Chris, and
pasted below.

"The acceleration of charge in an antenna results almost entirely from
the
applied potential difference at its terminals. The radiated fields
result
from the alternating current effectively passing through the radiation
resistance, and all the other, reactive, fields have no direct effect
on the
radiation resistance, or the component of the current that passes
through it
in phase with the voltage that is developed across it, which together,
of
course, represent the radiated power. The reactive fields affect the
terminal impedance and a large imaginary part can upset the device
trying to
send power into the antenna, but that is more of a system issue. The
alternating current that passes through the radiation resistance is
composed
of charge that moves in time with each RF cycle, accelerating and
decelerating accordingly. The electrostatic field developed between
the
ends of a half-wave dipole reaches its maximum value a quarter of a
cycle
later than the voltage at the drive point so any effect it has on the
charge
in the antenna elements during each cycle must be reactive, and it
doesn't
affect the radiation resistance or the radiated wave."

No it does not appear in Kraus book.

* That is incorrect, and I expect you know that to be the case. All of what I wrote above can be traced to sources such as Kraus, Jordan and Balmain, and Jasik; books you may never have tried to read and understand (on the basis of your comment).

He never followed Maxwells laws
with respect to equilibrium.

* Define 'equilibrium' in trems of normal physics and cite a reference.

To do that you must think in terms of
wavelength. After all with respect to science all revolve around
boundary laws of the Universe and you blindly ignore that fact.

* How is there a boundary to the universe? It is unbounded - the universe is known to be expanding into empty space.

Now back to radiation which applies spin to a p.

* No it doesn't - cite a reference.

Nowarticle where as
with a crt no spin is applied as it is heat that separates the resting
particle

* ... separates it from what?

Now earlier you refered to a electrostatic field that
according to what you stated did not have a border and surely you know
that just can't be unless it is in equilibrium which requires a closed
circuit.

* Fields in unbounded space tend to be unbounded. The fields around a
dipole are bounded by the surface of the dipole, which is the boundary
condition used by NEC, and usually in practice by the earth.

For this to come to fruition you go back to the boundary laws where
the arbitrary border is one that is closed i.e. in equilibrium.

* Define 'equilibrium' in terms of normal physics and cite a reference.

Now
cast your mind back to the Gauss extension where radiators and
particles lie in a closed static field. Now you should see that
equilibrium must reign for a closed static field. Now you blithely
mentioned an electrostatic field with nary a mention as to how it is
formed and how it fits into the whole picture.

* Recent discussion has been about the electric field produced by the
voltage that appears between the ends of a dipole - that's what I was
writing about, and so were you. How can you state 'with nary a mention as
to how it is formed'?

Why? Because the books do not provide an unbroken trail that fully
describes radiation
(books admit that) as I have done where everything dove tails into
the existing laws of the Universe.

* Kraus provides a trail that's as unbroken as can be comprehended by most
engineers. Physicists may wish to take it further but there's no evidence
of physicists in this newsgroup.

And then I gave you a bonus with
respect to the weak field that Einstein searched for in vain. Einstein
looked at the package presented by the Big Bag but omitted to keep
that which it was wrapped into.

* Is the universe enclosed in a Big Bag?

That was the arbitrary boundary around
which were forces or vectors that were equal and opposite when a
smallest of smallest of particles edged out towards the border. Yes it
was of a weak force but for all of that it broke the equilibrium
boundary as the forces at that point was not now equal. The breakage
was one where the opposing forces were offset to each other thus
providing a torque force that provided spin. Now we come to our own
Earth encased in a arbitrary border and outside the border we have the
same conditions of equilibrium that must equal the forces of the Big
Bang which means the outside has two vectors, gravity vector which is
straight and a vector denoting spin i.e. rotation of the Earth. On the
other side of the border you again have two vectors a straight vector

and that curly one you don't like me to call eddy current.

* Call it what you wish. Capitalising the word within a sentence, as you did before, is usually reserved for phenomena named after the people who discovered them - but that's an engineer thing.

Yup. Everything falls together nicely thank you, when you study radiation from first principles instead of binding yourself to books that readily admit to not understanding the radiation process.

* If you believe so fervently in your own version of all this then why don't you submit it to peer review at sci.physics or sci.physics.research? It's rather unfair to expose this only to an amateur radio newsgroup when what you are doing is apparently re-writing physics in such a major way. Those newsgroups would be more appropriate, considering the depth to which you are going (i.e. well beyond amateur radio) - wouldn't you agree.

Now
this is not being arrogant when one has applied all principles

* My dictionary defines 'arrogant' as: 'having or showing an exaggerated opinion of one's own importance , merit, ability, etc.' from the Latin 'arrogare': 'to claim as one's own'. Your re-writing of physics conforms to this definition precisely.

but I
do think it is arrogant of you and others to asasinate the character
of "S" purely because of his english and spelling and not to help one
that wants to learn.

* He is showing no inclination of wanting to learn - he asks a question, and then when answered responds with non-physical contradiction. His treatement here is a direct consequence of that behaviour, like yours.

Just think about it all. I have shown how a particle moves in space in
a straight line trajectory such that the particle maintains a straight
line without the parabolic force of gravity driving it down to the
Earth. Go back to your books and show just how the electrostatic field
came about and what was the borders that it was contained in
Art
via applied spin and where gravity

* As I say, you should present your theory to sci.physics and sci.physics.research if you have any interest in checking whether it is correct, and not limit its exposure to this group. Do let us know when you have posted there.

Chris

Here's what you are missing: RF is AC. At some point
in the radiation cycle, the instantaneous radiation has
to be zero at the zero-crossing time. That is when the
magnetic field energy is essentially zero and close to
100% of the energy is contained in the electric fields
at the ends of the dipole.

You cannot have it both ways. You cannot have a radiation
peak at a net current maximum time and also have a radiation
peak at a net voltage maximum time since they are ~90 degrees
out of phase. If what you are saying were really happening,
an antenna would radiate two times the applied frequency,
but it obviously doesn't.

Or did you not realize that when the electric field is
at its maximum amplitude, the current is close to zero-
crossing all up and down the standing wave antenna? The
phase of the feedpoint current is within a couple of
degrees of the phase of the current all up and down
the antenna.

That's why the current on a standing wave antenna cannot
be used to measure the delay through a wire or a loading
coil. All such "measurements" are bogus.

There is no radiation from a transmission line as long as the currents in it are balanced. Attaching a transmission line to a 0.05WL center-fed dipole does not change that balance.

The feedpoint of such a short dipole has very high capacitive reactance, so getting much current to flow into it would be difficult without proper impedance matching to the transmission line.

But whatever the impedance match, all of the radiation occurs from the 0.05WL dipole itself, and maximum radiation is generated at the feedpoint, where the r-f current is greatest.

> Could you tell us if the "almost double voltage" is the measured of
> theoretically predicted?

Since a voltage reference point is difficult to achieve
at the ends of a dipole, we rely on the conservation of
energy principle. Since the current is zero at the ends
of a dipole, all the energy must be contained in the
electric field. With that knowledge, the voltage can
be estimated.

Such is easy to understand by taking voltage measurements
on a 1/4WL open-circuit stub. If one uses resistance wire
for the stub, one can simulate radiation loss in a dipole.

The following is a transmission line simulation of a 1/4WL
monopole designed to run on the free demo version of EZNEC
available from www.eznec.com

http://www.w5dxp.com/stub_dip.EZ

The user defined resistivity of the wire is what causes
the 35 ohm feedpoint resistance akin to a 1/4WL monopole.
The 10 megohm load allows us to look at the voltage
across the "open" end of the stub. It is 1033 volts for
a 100 watt input. We can assume the forward voltage and
the reflected voltage at the end of the stub are equal
at 516 volts.

>The other factor is core saturation..

Hi Jim,

The only reason why a common mode choke (a more appropriate BalUn
construction for any application) would encounter "core saturation" is
due to the presence of a very significant common mode current - the
thing the choke (or BalUn) is supposed to suppress. If the "core
saturates" this is an indication that a common mode choke is very,
very necessary.

The better the choke (the higher its common mode Z), the more it will
snub the current. The more it snubs the current, the less chance of
"core saturation."

The solution to a hot BalUn is suppression of the current that is
energizing the "core."

As for:
>Karl Beckman wrote:
>> First thing to remember is a really radical thought: The power rating of a
>> voltage balun has to be decreased by the highest SWR factor existing on the
>> line.

I have NEVER heard this apocryphal "rule of thumb" before. For one
thing, it doesn't make sense on the face of it as it defines a linear
relationship between current (or voltage) with power.

Yes, we can all tell what is important to you. Unfortunately it does
not equate with what is important for you. No doubt that distinction
is lost in translation and you will continue to fumble on.

I'm glad to see you shed that nonsense about hydraulics. As you
understood that topic far less than RF (which is in itself on very
shaky ground), it wouldn't have done to poison the well.

This poor understanding is quite obvious by your last comment above.

The acoustic analogy predict it: "Between the nodes are places where the
amplitude is doubled. So the places
with doubled amplitude are standing. Pressure pulse travel.
In antennas is electron gas. The first place where the doubled amplitude
(amplitude means voltage or electron density) appear is end of the radials.
The next is halve wave apart from the end. Such places radiate strong
electric waves. They are the source of radiation."

Pick one of the above comments, only, Szczepan.

The feed points are terminals of the antenna. On center-fed dipoles
that are 1/2WL or less in length, antenna current is highest at those
terminals.

> How long are the folded dipoles and the
> loop antennas? Are there the short version?

They can be any length, but some lengths have better input
characteristics and/or more useful radiation patterns than others.

Sorry, 2*sin(2wt) <> sin(wt)

Here's the question: Is the radiated RF wave in phase
with the standing wave current or in phase with the
standing wave voltage? The radiated RF wave cannot be
in phase with both since they are 90 degrees out of
phase on the standing wave antenna.

Again, it is impossible for the voltage maximums and
current maximums to both radiate since such would
double the radiated frequency which it doesn't. We
usually transmit and receive on the same frequency.

You must decide whether the peak radiation comes
from the current maximum or the voltage maximum since
they do not occur at the same time. Until you make
that choice, rational discussion is not possible.

Surprised you dont know that!
Easily done. Boundary laws are based on Newtons laws where every
action has an equal and opposite reaction. So a subject under
discussion is placed inside an arbitrary border
where the forces of the contents must be equal to the sum of the
forces outside the boundary. Where does Krauss deviate from from
Maxwells laws? well for one thing his radiator differed from a full
WL or period so immediately he has strayed. Another thing is by
straying from a full WL he was unable to contain the electrostatic

field within a border
such as a quad. And it goes on especially with regards to his windings
pitch theory.
Thus the contents of the arbitrary boundary is now in a state of
equilibrium. this is true whether a unit of time has been added or not
to the equation.

> boundary laws of the Universe and you blindly ignore that fact.
>
> * How is there a boundary to the universe? It is unbounded - the universe
> is known to be expanding into empty space.

Hogwash. Nobody knows the extent of the Universe boundary. Every day
discoveries are made beyond our Universe so we are nowhere near the
point we can ascertain what forces
are required to contain a boundary.
Again I am surprised you didn't know that!

>
> Now back to radiation which applies spin to a p.
>
> * No it doesn't - cite a reference.

Well look at how salvage yards sort out metals into different
enclosures.
They apply a displacement current to a conveyor where each piece of
metal is elevated with spin such that it lands in the appropriate
enclosure which is dependent on the resistivity of the metal elevated.
This method of elevating scrap for recovery has been used for years
and it is the same action that is applied to particles for radiation.
Why would you need a citation for a practice that is well known and in
use? On top of that a citation is only an instrument to poin out who
and where the statement was made. This has its use for those who
easily believe what they see in print and thus save them from effort.

>
> Nowarticle where as
> with a crt no spin is applied as it is heat that separates the resting
> particle
>
> * ... separates it from what?

Now you are being silly. first the particle was resting. Then heat was
applied to its butt.
Now think about it. What fields are in place to take control of the
free particle that now has a increase in its potential energy?

Tend, tend. You mean you don't know? NEC is per the laws of Maxwell.
Equilibrium is a must as is the encirclement of a electrostatic field
just like a quad or loop antenna. Since the programmer did not follow
Maxwell in its entirety and frankly did many modifications such that
it would solve planar radiators, who knows what license the
programmers took to get the job done where it could foolmost of the
people most of the time?

I have concentrated on radiator that were in equilibrium and of a
closed circuit called a tank circuit
. You are mixing things up. I explained for somebody else what a
charge does for a radiator that is NOT in equilibrium because others
were unable to describe it adequately.

> Why? Because the books do not provide an unbroken trail that fully

> * Kraus provides a trail that's as unbroken as can be comprehended by most
> engineers. Physicists may wish to take it further but there's no evidence
> of physicists in this newsgroup.

No Krauss did no such thing. He expanded a yagi style radiator where
the elements ere made of loops. All he did was to connect them into a
continuous conductor. When experimenting with this he saw evidence
that field did not follow the axis of the windings
(rotation of the earth again) so he adjusted the pitch of the
windings to obtain a satisfactory pattern. He did not improve on the
existing knowledge of radiators as his radiators were not in
equilibrium and thus strayed from Maxwell.

So it is arrogant to do things for your self from first principles to
confirm whether printed matter is correct or not? Why would anybody
broaden the outlook of others work without determining that its
foundations was of rock or sand? Trust but verify seems very apt here.

Could be but he is not alone. He is surrounded by pseudo experts in
all fields who can prove nothing for themselves and relying on the
printed matter of others. Might just as well close the doors of a
library for a year to determine which book came out on top. Why on
earth would somebody turn him away from hydrolics when it like
electric current has laminar flow

My comments are addressed to so called voltage baluns. The above
explanation and my comments are not applicable to current baluns.

Your explanation of your Rule of Thumb is valid if the balun is located
at an impedance minimum for the stated VSWR. The explanation does not
apply at all in the opposite case, and to a lesser extent in all other
cases.

In many cases where the balun overheats, it is operating at an extremely
high current, and I^2R losses are not main contribution to heating.

The core material may only need to reach temperatures towards 200°C to
compromise the balun, the Curie point of some ferrites in use is lower
than 200°C. Thing is that the ferrite heats very slowly, and a 5 minute
test is not likely to raise the temperature to anywhere near the long
term temperature. That is good for us for many modes as they have high

peak to average ratio, but for the low peak to average modes / high duty cycle modes, the balun core may increase in temperature significantly for an hour.

The key thing is that assuming balun efficiency is very high is quite wrong, and when you start to think about balun efficiencies being below 50% under some extreme conditions, you realise the challenge in 5kW rated devices that are in small boxes and must not reach 200°C.

Well then, same general idea.. lots of volts = lots of flux = lots of dissipated energy from the core loss...

And, of course, not all baluns are made with appropriate materials (e.g. using a lossy EMI suppression mix might be fine in a "choke" application, where high Z is keeping the current low.. but terrible in a transformer type situation, where you have a lot of flux in the core)

So then, Szczepan, should transmissions using such antennas, and
expecting to be received on frequency "X" transmit on frequency "X" /
2 ? Note that such is not the reality.

Some low-level radiation from the transmit antenna may exist at twice
the carrier frequency, but in almost all cases it arises from
insufficient suppression of the 2nd harmonic of, and in the
transmitter.

And in NO case is it produced as you describe above.

Hi Jim,

A BalUn IS a transformer, and many of the lowest loss, widest
bandwidth ones are specifically designed to choke common mode
currents.

Such BalUns are NOT flux linked transformers and thus avoid working
(transverse) currents inducing loss and saturation issues.

It appears that the inference from your flux transformer terminology
>transformer type situation, where you have a lot of flux in the core)
is at cross purposes with BalUn best design.

Not exactly. The dominant loss mechanisms in "low frequency" ferrites
are essentially linear, and don't cause distortion. Saturation occurs
during a portion of each cycle, resulting in distortion. And saturation
doesn't always imply high loss.

> And, of course, not all baluns are made with appropriate materials (e.g.
> using a lossy EMI suppression mix might be fine in a "choke"
> application, where high Z is keeping the current low.. but terrible in a
> transformer type situation, where you have a lot of flux in the core)

A properly designed transformer has very little flux in the core -- the
flux is the vector sum of the flux in all the windings, which in an
ideal transformer is zero. The flux you do have is the magnetizing flux
due to the finite impedances of the windings, which you strive to
maximize just as you do in a choke (and the leakage flux which isn't
coupled from one winding to the others). So the best core material is
generally the same for a broadband choke as it is for a broadband
transformer. EMI suppression materials are very good for both, since
they're engineered to maximize impedance. An exception is where you're
dealing with enough power that the core loss is intolerable. For
example, a well designed choke or transformer might have only 0.5 dB
loss, a generally insignificant amount. But if you apply a kW to it,
you're talking about 120 watts of power dissipation, too much for a
small core. In those cases you have to use lower loss material, which
usually means lower impedance windings and consequent higher flux density.

This isn't exactly how such systems work. Abstractly the system is a
metal detector and a sorting table hanging off a CAN. A controller at
the other end of the CAN 'reads' the discriminator and 'writes' to the
sorter. The writes open and close ejector nozzles. These are the magic
devices that cause the material to 'elevate with spin'.

Richard,

It's not something I have control over using Outlook Express, and it has been commented upon by others before. Whether OE maintains the '>'s before lines of quoted text seems to depend on something in the text I'm quoting. I gather it is a known issue, and it's the reason why I sometimes use a '*' before the first line of new paragraphs of my response. I have been told I should ditch OE but I don't want to use webmail; I could use Agent but I haven't so far.

A new commercial radio hilltop vault is being installed in my area....
and the contractor has installed the tower and vault ground ring with
aluminum wire/cable, I have been advised. I do NOT know the gauge of
the wire, but I am curious what your thoughts are on this issue. I have
been involved the past 35 years of my career in a number of ground
installations and every one of those used large copper cable... no
aluminum anywhere. The last of these I saw was 6 or 7 years ago.

QUESTION: Are aluminum ground systems becoming common? Are they
reliable, even after absorbing some heavy strikes? Any other comments?

Ed K7AAT on the Oregon Coast

Isn't aluminium in the presence of air naturally coated with a thin layer of
aluminium oxide which doesn't conduct? In which case aluminium might be
fine for lightning conductors but hopeless for RF. What will the tower
carry? ... if it's all VHF and upwards then there's probably no problem.

My only experience with an aluminum wire ground system was one I laid many years ago in Denver, with buried aluminum radials. It was pretty badly corroded in a few years. But the soil there is alkali, not like the acid soil you have on the coast. Interestingly, aluminum corrosion is minimum at a pH of about 5.5 (see http://www.tpub.com/content/doe/h1015v1/css/h1015v1_121.htm), which is likely roughly what your soil is. So while there might be a lot of places where corrosion would be a problem your location might be one of those where it wouldn't.

If you know of any I would welcome their views. There are many retired
educated people in this world today that turn to that which they had
an interest with when young. Now it is difficult to get up to speed in
different sciences because various journals get the rights of various
papers from Universities e.t.c which are then denied to libraries and
the public.
This is a resource the country should assist because its costs are low
and where all have
large experience obtained thru their working years. Imagine
professionals who when retired
have twenty or more years of experience be allowed to follow and
contribute in areas where an interest has laid dormant for so long.
Today's efforts are applied to computers where data comes out in

bundles which have to be sorted to determine if anything good is being offered by using a mish mash of arithmetic formulae that are merged with similar formulae from different functions. Sad, sad, sad.

If you know of any I would welcome their views. There are many retired
educated people in this world today that turn to that which they had
an interest with when young. Now it is difficult to get up to speed in
different sciences because various journals get the rights of various
papers from Universities e.t.c which are then denied to libraries and
the public.
This is a resource the country should assist because its costs are low
and where all have
large experience obtained thru their working years. Imagine
professionals who when retired

have twenty or more years of experience be allowed to follow and contribute in areas where an interest has laid dormant for so long. Today's efforts are applied to computers where data comes out in bundles which have to be sorted to determine if anything good is being offered by using a mish mash of arithmetic formulae that are merged with similar formulae from different functions. Sad, sad, sad.

* It's true that a lot of effort is put into the areas that yield the greatest profit, and computing in one form or another does seem to have a grip at the moment. However, it is enlightening to take a look from time to time at news groups like the two I named to see the sorts of things they are discussing, and the _unbounded_ nature of the universe (which is what I wrote) is one of them. They too appear to have input from ex-professionals.

Have you ever tried to obtain access to a technical library in a university or one of the engineering institutions? You might be surprised how easy or inexpensive it turns out to be. As a member of the general public I have access to the IET library in London to read as much as I wish, and to photocopy.

Chris

Interesting. Can you point to an article or something on the web that
describes what you
say. For myself I have only run into articles by special purpose
machine manufacturers
who deal with sorting machines for scrap yards which deals with many
materials including plastics , glass etc as well as different metallic
materials. This sorting aproach that you mention sounds rather
interesting if they are relying on magic or voodoo!

However as far as NEC is concerned, your sad-sad-sadness applies only
to those (possibly even yourself) using computer software without
sufficient understanding of how it should be used, and applied.

Note that the U.S. FCC has endorsed the use of NEC in the licensing
process of many types of directional MW broadcast arrays -- given that
such NEC analysis was performed by someone with provable and
acceptable competence.

no, they are called electro-magnetic waves for a REASON! it takes BOTH fields to make up a propagating wave. So it is not the ends that radiate, it is the whole length where there are both electric and magnetic fields generated in smooth transitions of the sine wave, not in pulses.

Yes, some university libraries allow access to the public but not for
copies. These must
come from journals at quite high prices. Here you can be a member of a
professional society say IEEE but to get the journals of say antennas
and propagation then you must pay a couple of $100 to have access to
them. This is on top of the fees for the institution and the group
that you are personally a member of which also requires fees. But the
U.S. is not like being in London where you can take the tube to any
where such as the patent office library or visit the one on Birdcage
Walk (Royal Institution of Mechanical Engineers in the old days)
I am not aware of this IET that you mentioned. Here in Illinois which
is the size of the UK plus has a population that London sees every
day of the week! One library I would like to get into is on
Whitechapel road in Stepney (Queen Mary college) where extensive work
is done on antennas. Anyway what I do is to start right at the
beginning ie first principles
and with antennas stuck in a rut for so long it was a good one for me
as a retired person
to fiddle with as it was nice to talk to my buddies at BAC St Albans
and nearby towns when radio itself was a hobby for me but most have
now passed away. Now I have finished my personal antenna studies and I
will have to turn to the honey doos that have piled up over the last
few years even tho I have had a handy man come in regularly even so I

go thru periods where every thing that I own is broken and I must turn
away from my hobbies.

antennas don't have to be 'in resonance'.... a very short dipole radiates
almost as well as one 1/2 wavelength long... its all in the fields.

So you are back David ! have you built that four poster antenna yet,
of steel I presume,
for the top band? Hopefully the system of yours is in a state of
equilibrium so you can tell us good things about it. Did you have to
make a ground plane system? They are not needed for a system in
equilibrium so you may have displaced a lot of moles from their
habitat for no good reason. Haven't heard you mention anymore about
that book you were writing on antennas. I assume you do not have a
chapter about equilibrium as yet. And that problem you had about the
legality of turning a static field into a dynamic field, have you made
any progress on that yet (just pulling your tail)

Yes, aluminum is immediately coated by a few-molecule-thick layer of aluminum oxide when exposed to air. It's a non-porous, brittle, ceramic material commonly used for hybrid circuit substrates and for sandpaper grit, among other things. It's why aluminum, despite its extreme chemical activity, doesn't corrode -- unless the environment is capable of dissolving the aluminum oxide, which some are. Aluminum oxide is an excellent dielectric, into at least the microwave range.

But an insulating film doesn't make a conductor "hopeless" -- after all, the most perfect bare conductor is surrounded -- "coated" if you will -- by air.

Nor does a highly conductive coating degrade a conductor's performance. Only a layer of poorly conductive material of sufficient thickness is detrimental.

As I tried to make Art understand with respect to yagis, it's not necessarily resonant (or even usually), it's matched. By the matching network.

It was like releasing excess nitrogen containing waste into the wind, like all things are with Art.

See wall, hit with head, repeat.

Wow! No ground system needed for top band. The AM broadcasters are going to be all over this. Art, you are about to become very very rich. This overturns every measurement ever made on AM broadcast antenna arrays. You should be very proud that hundreds of engineers and their measurements were wrong.

Again, congratulations.

And you think I didn't know that like it was a personal secret of
yours?
I don't even remember discussing yagis with you. I moved away from
those years ago when I was building antennas with 80 foot booms and a
dozen or more elements all made of fishing poles with aluminum foil
surfaces. Now I am interested in antennas the size that Chip works
with but not with the same aproach. In fact I am committed to having
antennas made that are small enough for those with small gardens to
use, where how much money or land that you have allow you to run over
others is not a measure of ones skills. As for you you just sit on the
side lines with nothing to offer but insults since you appear to live
alone berift of friends. Try smiling instead of just growling and get
a life.

Well, let's take a look at some yagis from known companies, the US National Bureau of Standards and some well known hams. This is a small subset of the yagis I have models for. Almost all are HF or low VHF so we don't have to get into an argument over proper boom correction factors. Yes, something else you've never heard of, Art.

Cushcraft

Model Impedance at design frequency

215 23.9+j6.4
17B2 27.4+j8.3
20-3CD 17.9-12.0
20-4CD 18.7-j17.7
617-6B 36.4+j11.5
A147-11 24.9+j6.1
A50-5 28.6-j20.1
A50-5S 36.7-j10.9
A50-6S 25.2-j19.0

US NBS

NBS122 20.0-j4.8
NBS32 25.2-j7.6

HyGain

HG105BA 33.4-j26.0
HG155BA 20.1-j7.6
HG175CA 21.4-j27.0
HG204BA 25.8-j20.7
HG205CA 20.7-j22.4
HG215DX 27.7-j29.2

M Squared (or M^2)

2M5WL 24.9-j33.9
2M7 31.6-j10.4
6M2.5WL 40,2+j9.5

DL6WU (note this is the grandfather of the great 2m/70cm designs
like K2RIW, K1FO, and M^2 among others)

DL6WU 34.4-11.4

W1JR

W1JR3170 15.8-j17.7
W1JR66 29.2+j24.6

Note that none of these are particularly close to resonance at the
design frequency.

Art, you don't know what you're talking about. As usual.

Remember now Art?

2287. cordless phone range

Newsgroup: rec.radio.amateur.antenna
Date: 2009-09-23 02:47:17 UTC
From: David Hare-Scott <secret@nospam.com>
Message-ID: <h9c28a$3l9$1@news.albasani.net>
Source record: 12899

I have a 5.8GHz digital cordless phone system (two handsets and base station) that has reasonable range. It works fine inside the house and within about 30-50m of the house outside. The house is steel frame clad with cementitious planking and plasterboard lining, and has a steel roof.

Is it possible to improve the range of the handsets outside the house using simple supplementary aerials or by relocating the base station? If so where might I find design details?

I am competent with tools (I built the house) but don't know much about radio.

David

I really don't know what the point is that you are trying to describe.
Statements like the "design frequency "of the above antenna don't
really make sense if you do not provide what the intended design
frequency was in the first place.
On top of that, all the antennas that you point to could all be made
resonant in the right type of environment. Really there is more
important things than just getting rid of that which is to get rid of
your SWR meter since bandwidth, gain and many other things force one
into different judgements. All that you show may well be very good
designs but it is surely not a recommendation to avoid radiators that
are resonant in favor of those that are not exactly resonant as your
list shows

Is it possible that your definition of resonance means a resistive
impedance of fifty ohms?

You have made similar errors in the past is why I ask.

All antenna requirements have to be weighted to achieve what the
designer is aiming for, but nowhere is the degree of achievements
shown compared to the designers needs. So what exactly are your
judgement parameters of a good antenna and are they considered
universal for all environments?
I have given you a good opportunity to show off your talents with
respect to antennas Let's see how you use it or will you decline for

fear of exposure to the group
and fall back on a insult or two as you normally do ?

No congratulations necessary. The methods will be available to all
amateurs when the PTO print out comes about. All of this represents a
different aproach than that taken before me. If it is 90 % in error
where only 10% is useful that's fine by me as it represents an advance
supplied by an amateur who wasn't detered from experimenting by
others.
If I feel that something that is taken for granted is in error just
because an author had it printed in a book I will always step forward
if I feel the emperer does not wear any clothes.
Which of you have the courage to stand along side me knowing full well
your character will be dismantled before the true facts become known?

Hi John,

Thanks for your suggestion.
I'm surprised to receive so few answers to a problem that seemed very
trivial to me...
You can get dozens of answers for a patent problem but only one to a
daily problem that every ham has encountered at least once in his life
... ^^

Thanks and 73,
Patrick

Hi David,

I'm astonished you get as far as you claim. To get further can be
achieved, but the manufacturer and the FCC both conspire to make that
a difficult job (you don't see any antenna jacks do you?).

Apart from installing higher gain antennae on each unit, there is nothing
you can do.
The steel frame will act like a Faraday shield.
How far do you want the phone to work?

Practical problems have practical solutions - you got the most common
one that works. Same advice works for getting aluminum wheels off
brake hubs. That's pretty common too. Or get a bigger hammer.

If you want more correspondence, ask for a patented method - and then
try sifting the details from the obscure responses. There may even be
a method employing the weak force generated by the crippled Large
Hadron Accelerator. The corriolus force (twisting) might work too.

>that you are personally a member of which also requires fees.

Ummm... IEEE full membership is now $175/year. Membership in the
Antennas and Progagation group is $24/year.
<http://www.ieee.org/web/membership/Cost/dues.html>
That's about 4000 pages for the extra $24.

If you are a retired former IEEE member, currently unemployed,
disabled, or are working for only peanuts or stock options, you can
get up to a 50% discount on dues.
<http://www.ieee.org/web/membership/Cost/special_circumstances.html>

You can see the articles in each past issue at:
<http://ieeexplore.ieee.org/xpl/RecentIssue.jsp?puNumber=8>

If you're a cheap tightwad non-member, like me, you can buy individual
articles ala carte for $29 each:
<http://ieeexplore.ieee.org/guide/g_tools_apo.jsp>

If you don't mind just older papers, a member can buy the DVD with
everything from AP-S from 1952-2000:
<http://www.ict.csiro.au/aps/cdrom.htm>
for $100.

If you're a non-member, you really pay hansomly for the printed
publications.
<http://www.ieee.org/portal/cms_docs_iportals/iportals/publications/subscriptions/info/IEE
E_Sub_Price_List_2010.pdf>
For example, the Antenna and Propagation IEEE Transactions for a year
(12 issues) costs $1,200.

I think the most common 4:1 balun in use is the Rutroff 4:1`balun.

If it is constructed as a bifilar winding on a ferrite core, and the distance between wires is much less than the distance between turns (which is commonly the case), it can be though of as a transmission line wound on a core.

Rutroff suggested the transmission line equivalent in his original article.

I have developed a transmission line model and solution in the draft article at http://www.vk1od.net/balun/Ruthroff/RU1-4.htm . It predicts both low frequency and high frequency departure from ideal characteristics, and predicts core loss with different loads. The model suggests that balun efficiency can easily be below 50% on extreme loads using some typical commercial constructions. The model results have been validated on a small number of prototype baluns.

>Far-field EM radiation is produced only by the current flow on the
antenna, and that radiation contains BOTH the electric and the
magnetic fields.

For me the magnetic field is the illusion.

>You may have missed the accurate description posted by Chris, and
pasted below.

"The acceleration of charge in an antenna results almost entirely from
the
applied potential difference at its terminals. The radiated fields
result
from the alternating current effectively passing through the radiation
resistance, and all the other, reactive, fields have no direct effect
on the
radiation resistance, or the component of the current that passes
through it
in phase with the voltage that is developed across it, which together,
of
course, represent the radiated power. The reactive fields affect the
terminal impedance and a large imaginary part can upset the device
trying to
send power into the antenna, but that is more of a system issue. The
alternating current that passes through the radiation resistance is
composed
of charge that moves in time with each RF cycle, accelerating and
decelerating accordingly. The electrostatic field developed between
the
ends of a half-wave dipole reaches its maximum value a quarter of a

cycle
later than the voltage at the drive point so any effect it has on the
charge
in the antenna elements during each cycle must be reactive, and it
doesn't
affect the radiation resistance or the radiated wave."

My description is shorter:
The supply unit sends the voltage pulses (in opposite phase) in the
transmissing line. If such pulses collide the voltage is doubled and the
strong radiation take place. In straight radiator the forward pulse collides
with the reflected. In folded dipoles with that from the other wire.

In the Gas analogy radiate only the doubled voltage. The doubling take place
in the ends of the two radiators. The two spherical waves are radiated. So
some receiver antennas can work on doubled frequency (Luxembourg effect).

Yagis do have a resonant frequency but that frequency
is not at the design frequency. At the resonant frequency,
the forward gain and F/B ratio are not optimum. At the
optimum forward gain frequency and/or F/B ratio frequency,
the Yagi, sans matching network, is not resonant.

Point is, the Yagi radiation pattern sucks at the resonant
frequency, f(r). When one meets the designed-for radiation
pattern, i.e. gain, F/B ratio, beamwidth, etc., the Yagi is
NOT resonant at the design frequency.

That is about the same range I get on mine. I used to put my base
station upstairs to improve the range. This worked well enough to fill
some areas in my yard that were not covered. Some of the range
extending antennas for wireless routers may help. I think they are in
the same frequency range.

The Luxemburg effect is not produced by a dipole.

It has been ascribed to be produced in the ionosphere when two very strong EM waves cross-modulate. More likely it occurs when co-located, high power transmitters cross-modulate in their output stages due to coupling between their antennas.

> Now no vertical LW masts. But everybody has a
> horizontal dipole.

A horizontal dipole produces horizontally polarized EM radiation, which has very high propagation loss for the ground wave.

For this reason vertical polarization is universally used for LW and MW signals.

Agreed, although it has become popular to make designs with about 50+j0
driven elements lately. I think it's to make them simpler and lighter
because, as you say, the other characteristics are not optimum if you do.

Szczepan Białż˝ek wrote:
> In my antenna radiate the end where the voltage is doubled. In your
> something alse. What?

Unfortunately, the voltage doubling is accompanied by
transmission line currents at the ends of the antenna
which are known not to radiate. The reason is obvious.

When two currents are equal in magnitude and opposite
in phase, they do not radiate (much) because their fields
engage in destructive interference. These currents
are commonly known as transmission line currents but
also exist at the ends of a dipole as forward and
reflected currents.

When the phases of two currents are equal they engage
in constructive interference and radiate. These currents
are commonly known as antenna currents and exist at
the middle of a dipole that is equal to or less than
0.5WL long.

Unfortunately for your theory, since the standing wave
voltage is ~90 degrees out of phase with the standing
wave current (in standing wave antennas), the higher
the standing wave voltage the greater the destructive
interference between the forward and reverse currents,
i.e. the higher the voltage, the lower the radiation.

Sorry, but that is a simple fact of physics. If you
want the ends of a dipole to radiate, you need to
terminate those ends in the characteristic impedance
of the antenna in order to prevent transmission line
currents on the antenna.

If one models a 1/2WL dipole with the center 1/4WL part
horizontal and the 1/8WL ends vertical, one will get
a magnitude more horizontal radiation from the center
half of the antenna than vertical radiation from the
vertical half of the antenna. That's easy proof that the
center of a 1/2WL dipole radiates more than the ends.
The vertical radiation is 10 dB down from the horizontal
radiation even though equal lengths of horizontal and
vertical wire exists. Is EZNEC wrong?

Running the above dipole at double the frequency
results in equal currents in each 1/8WL of antenna and

indeed, the vertical radiation equals the horizontal
radiation.

If there is no current at the feedpoint terminals of a 0.05WL dipole
then there is no current anywhere else in it, and there would be no
radiation. Obviously that is not the reality.

The current distribution in such short dipoles is triangular in form:
highest at the center, and zero at the ends of the dipole arms.

There is no magic or voodoo involved with a controller area network.

There are all manners of industrial separators and practically all are
custom purposed for the user and the particular type of refuse
stream(s) they will be dealing with. It's certainly not a
one-size-fits-all industry. Most use a combination of methodologies.
Magnetic eddy currents are one means and their use in the industry
only goes back a couple of decades.

In a nutshell here is how eddy currents are primarily used in materials sorting.

As the eddy current roller spins it creates alternating polar fields. When inert (non-metallic) material enters a field a field of the same charge is generated around the object. As the roller spins the next field is of opposite charge to the field of the object and the object is repulsed. The momentum provided by the conveyor belt added to the repulsive force changes the trajectory of the object as it leaves the end of the conveyor belt. As a consequence inert objects travel further off the end of the belt.

Non-ferrous metals do not benefit from a charged field and fall straight down due to good old gravity. Ferrous metals are attracted to the roller and remain on the conveyor belt until they move past the roller on the underside of the table. Then those materials also fall straight down but at a different location from the non-ferrous metals.

That's about as useful as saying you do not obtain the maximum miles per gallon in your car when the ashtray is half full or when the carpets are at their optimal brushed out nap.

Thank you for confirming the use of eddy currents in the elevation and projection of scrap materials. My understanding is that the special purpose machinery industry has now advanced to the ability of sorting plastic and the like.

In one antenna can be only one mechanism.
In my antenna the current radiation is very weak.

Radiation depends on the shape of the ends. Thin vertical wire radiate in
horizontal plane. Tipped (big ball) vertical wire omnidirectional.
>
> Running the above dipole at double the frequency
> results in equal currents in each 1/8WL of antenna and
> indeed, the vertical radiation equals the horizontal
> radiation.

Look at the Kundt's tube. At doubled frequency in the horizontal parts the
new sources (doubled voltage) appear.
The sources on the horizontal wires radiate in all direstion perpendicular
to the wires.

The local Santa Cruz libraries are in serious financial trouble. The
main library has severely limited hours, while the satellite branches
are only open two to five days per week.
<http://www.santacruzpl.org/news/2009/jun/09/new-hours-all-branches-effective-july-1-2009/
>
None of the local libraries stock IEEE AP-S Transactions.

>Oh, and yes, If you have access to an engineering library on campus.

I joined the UCSC "Friends of the Library" association in order to
obtain an account. $35 to $60/year.
<http://giving.ucsc.edu/giving_detail.php?web_id=631>
Most IEEE Transactions are available online from off campus.
<http://library.ucsc.edu/gateways/gateways-for-visitors-and-neighbors>
Most colleges have similar arrangements. I would also join my alumni
association (Cal Poly, Pomona), which offers similar privileges, but
find the local college more convenient. However, there's a catch.
Most of the online IEEE AP-S Transactions are about a year or more
behind. The various libraries seem to prefer annual subscriptions,
which means most recent issues are often unavailable. If that
happens, I either pay the price of the download (only if desperate),
or borrow an issue from a friend with a subscription.

>Oh, and yes, if they let you back on campus..... Sorry, some (Art)
>have spit on too many professors.

Most of the stuff is available online. No need to visit the campus.
However, when I do, the real problem is parking. There isn't much
available. Going to the UCSC library is a major expedition for me.

I suspect that Art will be ok at a library, as long as he doesn't
bring his soap box and attract attention by loudly denouncing the
content of the physics, antenna design, or grammar books.

It was the vertical 1/2WL dipole. The doubled frequency was received in
England (I am not sure).
The same was in Warsaw (but collapsed - now is the monopole mast 1/4WL). The
doubled frequency was received in Austria.

>It has been ascribed to be produced in the ionosphere when two very
strong EM waves cross-modulate. More likely it occurs when co-
located, high power transmitters cross-modulate in their output stages
due to coupling between their antennas.

Now you have my description. Which one do you prefer?

>> Now no vertical LW masts. But everybody has a
> horizontal dipole.

>A horizontal dipole produces horizontally polarized EM radiation,
which has very high propagation loss for the ground wave.

>For this reason vertical polarization is universally used for LW and
MW signals.

Are now vertical dipole masts 1/2WL?

Frequency doubling is at all waves. To observe the frequency doubling the
both ends must have the same possibilities. The vertical dipoles have ends
on difeferent altitudes.

Nope, it's as useful as saying one cannot get the
advertised miles per gallon when one is driving
the car uphill at 80 mph. Miles per gallon is
related to incline and speed. Frequency, gain,
and F/B ratio are related. I surprised you don't
know that.

radiation. Obviously that is not the reality.

The simplest dipole is a transmissing line (the two wires).The standing
waves are always 1/2WL apart. The max current is always 1/4WL from the
standing waves. " In 0.05 no currents at all at the feed point" means, of
course, that the current is very very small.

>The current distribution in such short dipoles is triangular in form:
highest at the center, and zero at the ends of the dipole arms.

No such oddity in the reality.

David, before you give up, you can ALWAYS add an external antenna by
capacitively coupling the to antenna. Try this:

I live in a older triple wide manufactured home with aluminum siding.
The door bell on the front door was mechanical. There was no bell for
the back and no way to put in standard wired bells. I bought a pair of
electronic battery operated bells. The central unit always hears the
front door bell because it is 10 feet away and through glass windows.

The back door bell unit could not be heard by the control unit unless
the two doors leading to the outside were open. Not much good that
way. I cured the problem by drilling a hole just above the outside
push button unit and running a solid copper wire through the hole and
bent the end into a circle and left it close to the bell unit. Inside
the "mud room", I ran the wire several feet up and over a storm door
and along the ceiling toward the actual house. Still one aluminum
covered wall between the wire and the central bell unit. Now the
central unit always hears the back pus button unit. If it couldn't, I
was prepared to run the wire on into the house a ways.

So, try running a wire from the phone base unit to the outside of your
house. Experiment with length and placement to see if you get improved
distance. My electronic bell runs in the 300 MHz range, but may well
work for your unit, as well.

Good luck, Paul KD7HB

No matter how short a dipole antenna is in wavelengths, current is
always zero at the ends of each arm of that dipole.

The current distribution on a thin, wire dipole takes the form of a
sine wave. If the antenna is short, as in this case, then the only
part of the sine that can exist is nearly linear. Hence the
~triangular shape for the total current on the dipole.

Confirm this for yourself using Figure 2-2(b) on page 2-4 of the
following link.

Now that is interesting!
Visitors can only get on line if the University have them on their
list as being invited
Time period 45 days. I understand that you can't get copies because of
copywrite laws and oversite by the societies so I assume they get
freebees.
There is some pressure on lab schools to place results on the web
since it is public money. The Governor signed a bill a little while
ago on transparency as to where the money goes
But then nobody actually follow all the laws in Chicago and down
state.

My post states (not confirms) that eddy currents can be used but they don't work in the manner you suggested. The eddy currents are not solely responsible for the "elevation and projection" and there is no "elevate with spin" either. There is certainly no confirmation that the process is "dependent on the resistivity of the metal elevated" as you suggest.

>My understanding is that the special

Your understanding based upon what? Had you done a modicum of research you would have a definitive answer about the mechanisms used in sorting plastics and other non-metallic materials.

A little research beyond glossy brochures filled with marketing-speak can go a long way in aiding your understanding. You might use a search engine to locate manufacturers of sorting systems and query the manufactures for technical details on how their various systems operate. Your idle speculation based upon incomplete information serves no purpose.

That was about 3 years ago. The price these daze is $75.
<http://library.ucsc.edu/giving/friends/friends-of-the-library-membership-benefits>
Some other changes. See corrections below.

>Now that is interesting!

Chicago public library seems to have some IEEE Transactions:
<http://www.chipublib.org/search/results/?searchType=keyword&terms=IEEE&x=0&y=0>
but not Ants and Props. Typing "antenna" into the search box offers
117 books on the subject. That should keep you busy for a while.

>There is some pressure on lab schools to place results on the web

There's nothing that prevents you from joining the UCSC or other
university library and ignoring your local problems.

>> <http://giving.ucsc.edu/giving_detail.php?web_id=631>

Sigh. The link to joining the Friends of the Library seems to be
broken.

>> However, there's a catch.

Things have changed in the last few years. UCSC now contracts
directly with the IEEE for their online IEEE Transactions. No more
missing recent issues. However, I can't determine if Ants and Props
are available or even if the UCSC Friends of the Library are still

active. I'll inquire shortly as this is much cheaper than joining the
IEEE.

Source record: 12846

I should mention that the model and prototype measurements suggest that lossier higher μ cores may produce a more efficient device... it depends on ther things.

The tradeoff between core size, core material, number of turns etc for a given load is a complex one, more complex than implied by simple rules like "#61 is the best material for HF baluns".

Even the low frequency model of such a balun reveals this. If the balun is analysed using the techniques common used for a 50Hz or 60Hz transformer, the magnetising current (the current that flows into the transformer with no load attached) is design point. If the core is a low loss core, one could choose a relatively high mangetising current yet still have low H+E losses because the Power Factor of that magnetising current is quite low... or in the case of the RF transformer, one could use a relatively lossy material (high magnetising current Power Factor), but the higher μ of the lossier core means lower magnetising current, and the losses are acceptable.

The model I have proposed allows exploration of these different configurations, and the tools that I have developed allows solution of the problem using the core material frequency dependent characteristics.

I don't want to trivialise designing with magnetics, it is a challenge... but we can do better than simple rules like #x material is the best HF balun material... it is a very eHam approach.

Owen

BTW, the commonly held belief that powdered iron the material of choice for baluns is not soundly based. Such a view seems driven by the belief that lowest loss core material assures a good outcome. It is interesting that powdered iron has such a following, yet so little information is published on the core material compared to the ferrite materials.

As you say, though, there are always tradeoffs. A higher magnetizing current means a lower winding impedance. In a winding connected across a transmission line, this means adding a relatively low shunt impedance across the line. In a series connected winding, as in a current balun, it means less effective choking of common mode current. Maximizing winding impedance, which also minimizes magnetizing current, is always beneficial. But as we've both pointed out, sometimes we're forced to choose a material that gives us less impedance in order to lower the loss to a level that won't cause a problem at high power levels. The price is a smaller shunt winding impedance or less effective common mode choke, and also typically a narrower operating bandwidth.

You can also do it in a few seconds using the free EZNEC demo program. Open the Dipole1.ez example and the View Antenna display. Click the Currents (or FF Plot) button and see the current distribution in the View Antenna display. Then change the frequency to 3 MHz to make the dipole 0.05 wavelength long and click Currents or FF Plot again and see the altered current distribution. You can see the shape better by using the Current zoom control at the left of the View Antenna display.

As an additional educational exercise, compare the gains and patterns of the lossless 0.5 and 0.05 wavelength antennas.

Yes Roy, and none of this has visited impedance transformation... or the departure from ideal transformation that is envisaged by many if not most buyers. Choices for magnetising current and the TL Zo in my model of the R balun affect transformation at the upper and lower frequencies.

I know you have pointed out many times that shunting an antenna feed point with a resistor may improved system efficiency. At least one antenna manufacturer uses a lossy ferrite transformer to tame system efficiency in a wideband antenna... the CHA250 comes to mind.

No, actually I told you that I have the article plus one of the
important references as a PDF [file]. It's certainly not worth my
effort or the net bandwidth for me to try to repeat what that article
has already done a good job with. Also, I gather from some of the
postings in this thread that you're more interested in arguing and
being negative than in reading such an article.

Cheers,
Tom

Yes, no matter what the conditions on an ideal transmission
line, the two currents are equal in magnitude and opposite
phase. Therefore, zero radiation from an ideal transmission
line.

At the ends of a 1/2WL dipole, the forward current and
reflected currents are equal in amplitude and opposite
phase. Therefore, destructive interference with no
radiation.

At the center of a 1/2WL dipole, the forward current
and reflected current are in phase and interfere
constructively. Therefore, RADIATION!

Just to note that far-field radiation is produced, to some extent,
from all distances between the two ends of a 1/2WL linear dipole and
its feedpoint terminals.

Yes, if I am not mistaken, MOM assumes that the radiation
from each segment is proportional to the net current in
the segment. The maximum radiation comes from the segment
in which the forward and reflected currents are in phase.
The minimum radiation comes from the segment in which the
forward and reflected currents are out of phase.

The apetures in the frame are mostly about 1200mm by 600m and the members are 38mmx75mm. I expected that the signal would go right through with little interferance but I wanted check with the experts. If that is the case it seems to me that moving the base station outside the frame a bit which does little to alter the line of sight to handsets 50m away will not do very much good. Would you agree?

So the picture I am getting is that I coil some insulated wire around the base station's stubby aerial a few times and then run it outside the house and up high. Then play around with length and placement. Is that the idea? Is the guage of the wire significant?

I am only interested in the long term reliability of an aluminum ground system in comparison to the more common copper system. This is for lightning suppression only, I am not addressing RF issues. I am wondering if aluminum can handle the potential surge currents that copper can... and how well does its ground conductivity work when buried, when compared to copper.

No, actually I told you that I have the article plus one of the
important references as a PDF [file]. It's certainly not worth my
effort or the net bandwidth for me to try to repeat what that article
has already done a good job with. Also, I gather from some of the
postings in this thread that you're more interested in arguing and
being negative than in reading such an article.

I have used "library" many times in my posts in meaning "read something". I
am here to collect the arguments that EM is useless. So I am interested only
in troubles in explanation of antennas behaviour. You should agree that now
we should analize the behaviour of electrons in antennas. The first antenna
(Hertz experiment) was made before discovery of electrons. But electronic
oscillators use electrons which travel in vacuume . They have the charge and
the mass. In antennas are the same.

For surge currents only, Al would need to be thicker than Cu of equal handling capacity. If you are stressing things to the max, Al has a lower melting point.

It would work for RF ground also. The oxide layer would not affect the performance. Lots of us use insulated copper wire for ground radials.

Only concern I would have is that the electrical connections are properly made. AL's talent for oxidizing has been a problem in the past with house wiring.

Well, its pretty hard to improve on John's method. 8^)

In the interest of furthering the conversation, it might turn to what to do about that corrosion and general poor looks of the aluminum at present

Some folks advise using steel wool to remove the surface tarnish, others caution that particles of steel will embed themselves in the tubing and cause rust.

There is brass wool that would negate that, as well as Stainless or copper wool.

If you really wanted to pretty the thing up, you could chuck the elements in a drill and use aluminum polish.

One thing that I might try the next time I have to do this is to use some motorcycle wheel cleaner on the tubing. It works a trick on my bike's wheels. You spray it on, then brush it around, then rinse it off. Wear gloves and don't let it sit too long, as it's a bit caustic.

Then the really big thing is upon re-assembly, you'll really want to use some oxide prevention creme on every joint. I've bought some at the local Hardware store, it's inexpensive and a tube will last a lifetime. Sounds like the original assembly didn't use that.

The OP referred to a 'vault ground ring', not radials.

Furze is a major supplier of lightning protection products in the UK and
they don't favour aluminium for earth connections:
http://www.furse.com/elp/earprod.htm. I understand copper and
copper-plated-steel is still used for neutral earth connections by UK
electric power supply companies as well - the oxide layer on aluminium and
its alloys, if present, must have some value of breakdown voltage and
anything that elevates neutral above earth that can be avoided has to be a
bad thing.

Those 3M 'Scotchbrite' pads work well too. There's a surface treatment that used to be known as 'alochrome' (or similar spelling) in the UK that does wonderful things to aluminium alloy surfaces - it's just a dip (but its probably a combination of substances prohibited by the HSE nowadays).

Don't coil it around, just place it near to the antenna. At the most,
just a single loop around the base of the antenna. Gauge is not
important.

Hi all,

Thanks for these constructive answers...
My problem is that a local ham passed away and his widow asked me to
remove all antennas.
The only yagi he had was a 203BA. For transportation and reuse of this
antenna, i need to dismantle it. I was not able the separate the boom

in 2 pieces nor could i dismantle 3 half elements.

My first problem is the do that without breaking or deforming something. Once this has been done i will clean the element parts that have to be in contact together. I will leave the other parts corroded by the aluminium oxide which is makes good "natural" protection.

I will try to heat the joints, all my other efforts did not help... Unfortunately i could not carry the parts in my small car and i have to wait the widows return to continue my work.

I was thinking of a chemical solution to remove the oxide without any pain, but i think i will continue as far : "may the force be with you".

Thanks,

Maxwell was the genius Such are almost always right. He assumed that
electricity is the incompressible massless fluid. But up to now nobody has
isolated the pure electricity. We use only the charged bodies. The electrons
are also like charged bodies. They have mass. EM was made for space. We here
analyse the electrons in the conductors. If electrons are not a pure
electricity when the EM is useless for conductors. Maxwell wrote the
"Treatise on electricity and magnetism" not "Electrodynamics of charged
bodies".
It seems that EM is useless for antennas. I do not know what is in space.
May be that there EM is usefull.
How do you see it?

"The Umov-Poynting vector[6] discovered by Nikolay Umov in 1874 describes
energy flux in liquid and elastic media in a completely generalized view."

Poynting "discovered" it in 1884.
"He was the developer and eponym of the Poynting vector, which describes the
direction and magnitude of electromagnetic energy flow and is used in the
Poynting theorem, a statement about energy conservation for electric and
magnetic fields. This work was first published in 1884. "

The same is with Maxwell math. Helmholtz wrote such for his whirls.
Many people are thinking in the same time about the same think.
I am not alone in the "Acoustic analogy".

Any wire that is excited at a wavelength where the wire is
significantly longer than one wavelength, then this wire stands the
high chance of turning into an end fire antenna. This means if that
wire goes up, so will the signal - straight up (with any number of
very minor lobes in all other directions).

Hi, Richard.
I learned of this trick many years ago, 1960's time frame. Portland drilled a second tunnel through a ridge on West Burnside street, making it two lanes each direction. Drivers began complaining that their radio reception always went out when they entered the tunnel. Duh!!! Everyone said nothing could be done, This was the way radio worked.

One engineer said he could fix it. They mounted insulators in the tunnel ceiling, and strung a wire the full length of the tunnel. On the East side, they ran the wire up somewhere on the hillside. I never was able to determine just where it went. The antenna picked up the local am/fm signals and radiated them in the tunnel. Drivers could continue to listen to the radio when they went into the tunnel. Volume was reduced sometimes, but reception continued.

I wonder if hf and vhf ham radio operation is possible in the tunnel?

I see the same wire trick in other tunnels. The I-90 tunnels East of Seattle have the wire.

and you call yourself a Ham? Just where did you get the idea that you
can couple to a 5.8 Ghz Antenna, by wrapping a loop around it, and then
feed an External Antenna? Sonny, this may work for you, at 0.0 - 200 Mhz,
but it sure isn't going to work at 5.8 Ghz.

For Lightning Protection Aluminum is NOT the grounding material of
choice. Higher resistance per foot. (Less conductivity) and the Oxide
boundary layer, make it unsuitable for this type of use. For RF Grounding
use, it will work just as well as copper as the Oxide layer really has
no effect at RF Frequencies.

A good point.

The National Electric Code has some fairly specific requirements for how grounding system connections must be made. Soldering is not permitted, as the high temperatures which can occur at such connections during a lighting strike can blow the soldered connection apart. Strong mechanical connections, or welding (e.g. "CadWeld" thermite-type welding) is required.

I just ran across the following:

http://www.homeinspector.org/resources/journals/Intro-Electrical-Grounding.pdf

It indicates that the NEC forbids the use of aluminum conductors for grounding "where in direct contact with masonry or earth. Aluminum conductors require 18 inches of clearance from earth." (NEC paragraphs 250-91a and 250-92a are cited).

There's also a note on the citation: "ATJ note: we have field reports of complete failure of uninsulated bare aluminum grounding conductor wire when it was not properly protected from corrosion - for example where left touching a masonry foundation wall."

It sounds to me as using aluminum wire as a lightning ground system is a poor idea.

I've never seen any that use aluminum wire. Everything I've seen and
what little I've done was copper wire for both mountain top and home
grounding.

The National Fire Protection Association (NFPA) has guidelines such
things. See NFPA 780 "Standard For Installation Of Lightning
Protection Systems 2004". It describes protection for people,
building, and property from lightning damage.
<http://www.atmo.arizona.edu/students/courselinks/spring07/atmo589/articles/NFPA_780_2004.
pdf>
1.1MByte PDF. Several sections mention aluminum use.

Googling merrily...

<http://everything2.com/title/aluminum+wire>
The only problem you have to consider is that you cannot
allow the wire to enter the structure because exploding
aluminum can cause a fire.

<http://electrical.about.com/od/electricalsafety/a/lightningprotectionlightningrods.htm>
The underground connection to the lightning protection system must
be made with copper wire because underground connections should not
be made with aluminum wire. Aluminum wire will corrode when placed
in the ground. The National Electrical Code requires the aluminum
wire connection be at least 18 inches above the ground [NEC Section
250.64(A)] with a bi-metal splice. This connects to an eight-foot
copper ground rod at least two feet from th home's exterior wall.
There must be a minimum of two ground rods installed to the system
on opposite ends of the home, with one near the service entrance
ground rod so it can be bonded to this ground rod. This ensures
that there is a common ground between all ground rods. This should
make the connecting copper wire length between the ground rod and
aluminum cable approximately four feet long. Place the ground rods
diagonally on either end of the house, not exceeding 100 feet
between the two ground rods. If this distance is exceeded,
additional ground rods must be added to ensure proper grounding.

<http://www.glenmartin.com/catalog/lightning.htm>
They use copper wire, but the lightning rod points are aluminum.

<http://www.lightningrodparts.com/faq.html>
(13) Will Aluminum Wire/Cable and Rods work as well as Copper?
It should as long as the installation rules are followed.
Certainly Copper is a better conductor than aluminum but
the Aluminum cable is larger than the copper therefore making
up for aluminum's lesser conductivity.

(24) BASIC INSTALLATION DETAILS:
No Structure shall have less than 2 ground rods (Aluminum wire
should not be underground)

Below is good information, but only applies to electrical systems' grounding... not commercial radio vault lightning ground systems. Also, the aluminum system I came across certainly had crimp or other mechanical bonding methods which avoids the connection issues discussed in the NEC.

I have no control or great concern on this, but was surprised to see aluminum for my first time. I just wondered if it was common.

Hi,

Saw a picture somewhere of an in-line lightning protector for a HF radio
receive only antenna.
Coax style.
Apparently has the typical gas tube, and when activated shorts the center
conductor to the braid.

Was wondering a bit about this.

I seem to remember in the old days, there was always a third tap on these
sort of things that you ran a solid ground to, e.g., a water pipe.

Does merely shorting to the braid provide "good" protection ?

Any thoughts would be appreciated.

Also want to ask: what about voltage surges of a few hundred volts or so
induced on an antenna lead from a nearby lightning strike perhaps
.
The levels way below what would trip a gas tube I would imagine, but still
more than enough to ruin a front end of a receiver.

How does one protect against these without breaking the bank doing so ?

Thanks,
Bob

The only time in my life that I saw aluminum corrosion was when I
spotted aluminum tubing sticking out of the ground at the house. It
just made a pile of aluminum dust!
I have no idea how a ground plane would work if the aluminum opened up
in time in different places, so sticking with copper seems the best
way to go. If I had a problem with radiation my mind would be pointing

at the aluminum every time so why the hassle?
You never know what state your ground is in these days because the
builders spread building garbage aound before they spread the grass !
Now we have acid rain to think about.

There are two issues, the differential impulse, and the common mode
impulse.

The shunt gas discharge tube will fire on the differential impulse
voltage, although relatively slowly, even if it includes a radioactive
isotope to assist ionisation.

More importantly perhaps is that there is likely to be a substantial
common mode current impulse and that will induce a transient voltage
gradient in your grounding system. That transient may cause potential
differences across equipment interfaces generally, possibly sufficient to
damage them. There is also a risk of injury or death to persons.

The type of suppressor you describe does precious little to deal with the
common mode current impulse. The 'third wire' assists shunting common
mode current to ground before entering the equipment room.

Disconnect antenna conductors when not in use, and do not use them unless the probability of lighting is low?

EM (photonic) waves travel at the speed of light in the medium.
EM (photonic) waves do not travel inside conductors. EM (photonic)
waves travel in space near to the surface of a conductor. For an
HF wire antenna, the photonic waves travel in the space surrounding
the wire and some is radiated. For a wire transmission line, the
fields of the photonic waves tend to cancel and not much is radiated.
For a wave guide, the photonic waves travel in the space on the
inside of the wave guide and very little energy escapes the conductive
sides of the wave guide.

The purpose of using a conductor with free electrons is that the
free electrons are capable of emitting EM waves in the form of
photons.

1. Without the photons, there would be no radiation.

2. Without the free electrons, there would be no photons.

3. Without the metal conductor, there would be no free electrons.

It is a very simple cause and effect chain from the aluminum or
copper antenna to the release of photons as radiation. I think
my 12 year old grandson could understand the principles involved.

Sorry for the triple posting, I didn't think they got through.

Surely, someone on here knows these formulae and how to work them.

THANK YOU.

I read all three posts, and it was a bit hard to understand your problem.

Firstly, the formulae on the Wiki page that use the log term are approximations of the function using the cosh term, and the approximation is poor for small S/d.

Have a look at the calculator at http://www.vk1od.net/calc/tl/twllc.htm , it uses the cosh term in its calcs. BTW, the metric equivalent of your example is 2mm wires spaced 150mm.

Hi Bob,

It takes about 100 volts for the neon tube to strike. The back to back diodes in the receiver antenna input should protect against this. The duration of a lightning strike is so brief that insufficient heat will be generated to destroy the diodes.
BUT
The neon or any spark gap protection device cannot protect against a direct lightning strike, only a near miss.

Shorting the coax centre to the braid may not be good electrical practice but will provide sufficient protection for all practical purposes against static build up and lightning strikes within around 100 yards from your antenna.

When at sea in the merchant navy a similar system did withstand a direct hit while I was in the radio room. The whole room lit up with a blue glow and there was a terrific crash from the antenna switching box as the strike arced to the ground through the ship's superstructure. Probably helped to have 20,000 tons of steel in contact with the ocean!

The receiver (Marconi Apollo - wadley loop tuning and digital frequency readout on nixie tubes) blanked for about 5 seconds and then came back. Marconi know how to build stuff in those days. :-)

Any protection is better than nothing, a spark gap (old automobile spark plug) or small neon tube, a couple of back to back diodes and a 5 megohm or higher resistor across the diodes to provide a static discharge path will do the job for pennies.

Regards

Mike G0ULI

... not doing too well thismorning, too eager to get out to breakfast.

I also meant to note that the log formula is 276log(S/d) using the same notation as the acosh formula.

The authors have cobbled formulas from different places, and they do not use a consistent meaning for S and d.

But, use the acosh formula for close spacings.

as most of these may.

I do recall taking an early (probably the first) Collins digitally tuned receiver to a coast radio station for evaluation. It had inverse parallel diodes across the RF amp input for protection of the FETs and was totally unusable as when the on-site 500kHz transmitter was keyed up, it wiped out all of the receivers (not just this one) with broadband noise. It took a few minutes to realise what was causing ALL of the ROs to hear the station callsign, not as a beat note, but as noise as if it was near to where they were listening and just needed to be tuned in. Whilst the Collins was connected to an antenna, it caused havoc, even if powered off!

Beware of the effects of inverse parallel diodes across the antenna.

You are correct in your analysis on transmission lines and radiation
and also with your linkage to other sciences such as water flow,
lamina make up.
Einstein made the connection to the standard model and it's four
forces. These are in constant use in our Universe so yes the
mathematics are intertwined. But there are many things we do not
understand about electricity and magnetics such as the fields that are
generated consist of.......what? Mass, elastic energy e.t.c?
So at this point it would be futile to rid yourself of EM as you would
also be ridding yourself
of 1/4 of the Standard model which has not entered the Universe as a
garbage thing.
To join the mathematics as applied by the Standard model to sciences
of the Universe is very idealistic but doable. But at the same time
mathematics has lead us to this present stage with respect to
radiation where with all the tools that scientists have now have not
been able to close gaps in radiation as we know it to this day. Look
at radiation and try to connect it to light and heat emmisions. The
last two science see them as rays, For
radiation ala antennas it is seen as waves, magnetic waves when we
know that intersections of such create distortions, deflections and
even cancellation. So why not begin with one of these problems from

first principles to find a single opening of contention to build a new theory upon. The odds are that the required evidence is already out there
where it is constituted on both mathematics and observation thru the ages rather than something that popped out of a computer where you have to do all the observations from scratch as to where this new formula fits in. Since you are looking at acoustics why not start with PV=WRT
which actually consists of forces stated in the standard model and thus force
constituents of all the sciences, a treasure chest of guide lines and information. You are searching for the new where all on this group resist change from the old. Your treasure chest does not lie here only minefieldsand decaying sign posts.

Sorry, I was wrong there, they are 'correct'... 276log(2*6/0.08) gives 600 ohms which is the correct answer.

Check that the graph you are referencing uses the same meaning for the two dimensions.

In the time honored tradition of destroying a joke by explaining it, Richard made a remark about the OP's noting that other threads get a lot more traction, namely the Coriolis thread of Arts'. That one had a lot of posts. The twisting was the obvious reference to Arts' theory, which was combined and brought home with the necessary twist on the antenna elements. Finally, the spelling - well, Art has been known to make a few spelling mistakes. We're talking three levels of joke in one here!

Not so!

For example in this month's QST magazine there's an article on using a 40m full-wave loop on 80m. The designer uses a series quarter-wave section of 450 ohm ladderline to make the impedance "more manageable". He quotes 300+j8000 at the antenna end of the ladderline. Now plug those values into Owen's calculator, using something like Wireman 551 for the line, and you'll get 7dB of feedline loss.

Steve,

It may even be worse than that as TLLC models skin effect in a homogenouse conductor, and some ladder lines use copper clad steel that will have higher loss at the low end of HF where the coating thickness is less than several skin depths. This is especially true of the more expensive stranded CCS types.

But, yes... QST runs stories from time to time that reinforce the myth that ladder line is so good that you *never* need to consider its loss.

Here is are reviews of a couple of older articles discussing the relative merits of ladder line and coax:

Hi Paul,

You can get the same thing going through the tunnel north of the
Golden Gate bridge (this from my experience of 50 years ago).

What these couplings are, for AM at least, are evanescent waves, what
current science calls Plasmons. Others here cut and paste reports of
Tunneling (of the relativistic kind, not the hole in a mountain kind)
- all the same thing, none of which is understood by those who simply
push the copy button on a Xerox.

As the frequency rises, however, it is harder to propagate that energy
90 degrees off the wire unless you are within one quarter to one third
of a wavelength away (which now brings rise to parasitic coupling - as
I said all of this is the same stuff).

A lightning bolt is a transient so its current must be composed of components having a wide range frequencies. Consequently lightning conductors need small self-inductance as well as small resistance to work properly.

If you're not convinced after reading the responses, turn on your radio the next time a lightning storm is anywhere nearby -- or for that matter, anywhere within skip propagation range. Then explain how it is your radio is hearing DC.

Indeed Roy, rather than argue that lightning doesn't contain AC
components, one could more cogently argue that it is *not* DC.

It is evident that many hams treat lighting as DC in the design of their
lightning protection system (eg small conductor diameter, sharp bends,
loops, u-turns etc in down conductors), but if you pick up the simplest
models for analysing a lightning down conductor, they treat it as excited
by a double ramp current, and the down conductor as an inducance.

Such a model is not a DC model.

Owen

>You are correct in your analysis on transmission lines and radiation
and also with your linkage to other sciences such as water flow,
lamina make up.
>Einstein made the connection to the standard model and it's four
forces. These are in constant use in our Universe so yes the
mathematics are intertwined. But there are many things we do not
understand about electricity and magnetics such as the fields that are
generated consist of.....what? Mass, elastic energy e.t.c?
>So at this point it would be futile to rid yourself of EM as you would
also be ridding yourself
of 1/4 of the Standard model which has not entered the Universe as a
garbage thing.
>To join the mathematics as applied by the Standard model to sciences
of the Universe is very idealistic but doable. But at the same time
mathematics has lead us to this present stage with respect to
radiation where with all the tools that scientists have now have not
been able to close gaps in radiation as we know it to this day. Look
at radiation and try to connect it to light and heat emmisions. The

last two science see them as rays, For
radiation ala antennas it is seen as waves, magnetic waves when we know that intersections of such create distortions, deflections and even cancellation. So why not begin with one of these problems from first principles to find a single opening of contention to build a new theory upon. The odds are that the required evidence is already out there
where it is constituted on both mathematics and observation thru the ages rather than something that popped out of a computer where you have to do all the observations from scratch as to where this new formula fits in. Since you are looking at acoustics why not start with PV=WRT
which actually consists of forces stated in the standard model and thus force
constituents of all the sciences, a treasure chest of guide lines and information. You are searching for the new where all on this group resist change from the old.

They are the practicians. They know the evidences. Only teachers "resist change from the old."
I know evidences about the Gas analogy from the pneumonic control systems and many others branches.
Now I am collecting the evidences from the radio waves people that the voltage radiate not current. I pick-up a lot.

When using aluminum, always use one wire size larger than what is specified for copper wire. I've seen aluminum used in telephone company ground fields for years, I don't think the corrosion is any worse than copper. Always use a no-oxide "grease" when connecting aluminum to a different metal, like copper or a lot of corrosion will occur. Do a "Google" search on the subject and you'll probably find all the information you want.

Hi Paul

More for interest rather than on topic.

I use to work for the company that did a tunnel rebroadcast systems for a series of motorway tunnels in Sydney (Australia) back about 5 years ago.

It had to cover a number of operating freqs, mainly AM, FM, cell phones and certain VHF/UHF comms. Most were active rebroadcast and effectively were same frequency linear repeaters. The tunnel helped not letting radiation out as well. Reradiating was done with two cables the length of the tunnel. AM was a single wire and the rest was via leaky coax. The single wire was resistive terminated at one end and coupled with some large toroidal transformer at the source end. I dont remember all the details but think that the toried had multiple inputs.

We also had a class A amplifier system on a UHF freqency. (about 401MHz from memory) It had two yagis spaced maybe 20ft apart facing opposite directions in the tunnel. Enough isolation was achieved to not cause feedback and of course we had a second pair of yagis stacked above that for the other direction.

You even find "mine comms" systems that work in a similar vein.

Interesting story about the Portland & Seatle systems, thanks!

Cheers Bob VK2YQA

Lightning is pulsed dc. The pulse can be examined by fourier analysis,
as every sophomore electrical engineering student knows, revealing that
the lightning pulse is made up of a superposition of ac waves of many
frequencies.

One can get away with explaining some things about lightning using
simple dc analysis but most of the interesting stuff requires ac
analysis.

And then there is the business of a nearby lightning strike raising the voltage of ground lines so that during the strike; they are no longer at ground potential. This requires ac analysis with impedances rather than resistances.

I think we're arguing semantics on this. I spoke in pure terms... there is no argument that Lightning itself is a DC current. The fact that it is so short may bring the other RF issues to play, but that is not where my thoughts were when speaking on the DC issue..

Ed

Well, actually Lightning is a Pulse of DC, which causes ANY conductor
that it reaches to "RING" which is then AC, as it dissipates...
So, it has Both components.....

Semantics are important when the goal is communication.

Lightning induces extreme currents in nearby conductors, and radiates strong fields covering a wide portion of the radio spectrum, both characteristics of its RF content. High voltage DC transmission lines, for example, don't. While you could correctly call lightning "pulsed DC", it's certainly not correct to say it "isn't RF". As other folks have pointed out, effective lightning protection requires a solid understanding of its RF nature.

Hi Owen,

Point taken. The standard Marconi ship station fed the receive antenna through the back contacts of the key, so the receiver was always disconnected whenever the transmitter was operating. I remember having to pay about ï¿½15 extra for my CMOS TTL electronic keyer to be fitted with a changeover relay rather than direct keying so I could use it with the standard Marconi ship installation. Still working fine today after 34 years of use!

I don't recall ever operating close enough to any other stations for the diodes to cause me a problem, although I did once upset a Russian warship when operating from Angola. My signals were apparently overloading their equipment...

Resonance means little. It is like reverse engineering where it is
assumed or understood that the transmission line will be 50 ohms! The
point to remember is that the less the resistive component that one
measures at the antenna the more the power is shifting over from the
resistive loss to the radiative resistance and nothing more. For
matching there is an advantage when the load is totally resistive
because the matching becomes less complicated. Obviously as more
energy is shifted over to radiative purposes it is more difficult to
feed as we do not know how to switch power transmission from a
parallel line to a singular line. But the fact remains, the less the

resistive losses the more power goes to radiation which is exactly what you are trying to achieve.

It is truly amazing the things that come from his keyboard. This one statement proves he understands nothing.

And he contradicted his previous stand on resonance, too! 2 in one blow.

Oh dear, Art. That particular little jibe is used to rib folks who agree with each other these days, and has gone way past the idea of anyone suggesting that someone else is gay.

I was myself making a very loose reference that in some cases on the internet, two different people might actually be occupying the same room in exactly the same place because sometimes two different personalities might actually be the same person.

I have no reason to suspect that you are either of these things.

I do not agree or disagree with "S". I just don't like it when people
gang up on a person while being shielded behind a keyboard. There is
absolutely no need for insults from those
who apparently know less but merges with a mob attack for personal
security but with the intent to hurt and harm.

The list is by Alexander Shimansky UR5SAS.

I totalled the Amazon prices. $801.74. Amateur antenna design is
becoming a rich mans hobby. However, there is hope. When I look
under the "buying options" buttons, there are cheaper editions
available. I only have 3 of the 10 books listed. Sniff.

What a tempest in a teaspoon.

At the risk of Art summoning up another mouthful of saliva to cast
upon anything British, a quote from P.G. Wodehouse comes to mind:
"He was either a man of about 150
who was rather young for his years or
a man of about 110
who had been aged by trouble."

Pushing that saliviathan risk to the edge with Oscar Wilde:
"My dear Algy, you talk exactly as if you were a dentist.
It is very vulgar to talk like a dentist when one isn't a dentist.
It produces a false impression..."

See:
<http://www.polyphaser.com/productdata.aspx?class=coax>

This is what I use on the local mountain top sites.
<http://www.polyphaser.com/cms_spol_app/Translations/English/B50.pdf>
Note that we don't have much lightening on the left coast, so I don't
have much history on how well it works. The one site where we did
take a nearby hit, managed to blow up some unprotected ethernet to
coax translators, and some cheap sacrificial ethernet switches.

Also, not all lightning protectors use a gas tube. I have an older
Polyphaser with ZnO ceramic elements. When hit with sufficient
energy, the ZnO expands and closes a gap. Polyphaser places 4 of
these in series from the center conductor to ground. My guess(tm), is
that when hit by lightning, one of them might stay shorted. 4 hits,
and it's totally shorted and must be replaced. However, I'm not sure.
I'll post a photo when I find it.

>Was wondering a bit about this.

Articles on the subject.
<http://www.polyphaser.com/technical_notes.aspx>

Ham Radio protection:
<http://www.polyphaser.com/cms_spol_app/techdocs/Ham%20Radio.pdf>
See Pg 6 for some interesting comments on receiver protection. Quoting
in part:

Coax protectors should be units that have dc blocking on the center
pin. This serves as a high pass filtering that prevents the
lightning's low frequency energy from continuing to your equipment.
The strike energy is picked off and diverted into the ground system
in a controlled way. The dc blocking ensures the operation of the
protector regardless of the input circuitry of the equipment.

Did you know that spark gap protectors with dc continuity will not
work on receivers and shunt fed duplexers? The shunt to ground
inside a receiver (coil to ground for static draining) prevents the

low frequency lightning energy from turning on the dc continuity protector. The coil shunts the energy to ground all right, but it is at the wrong place. If the coil can't handle the energy (half the coax surge energy is on the center pin), the coil will open up and the current will translate to a large open voltage source capable of arcing anywhere within the radio.

>I seem to remember in the old days, there was always a third tap on these
>sort of things that you ran a solid ground to, e.g., a water pipe.

Yep. The current needs to go somewhere to get to ground. Best through a big fat wire ending in a good ground than through your equipment. Incidentally, a water pipe is not a decent ground for lightning protection.

>Does merely shorting to the braid provide "good" protection ?

No. If lightning came down your coax cable and to shorted braid it must have a path to continue to ground. Just a shorted coax will send it through your equipment, probably through the AC power cords, and then through the house wiring. I've seen photos of the wall blown out when that happens. Bad idea.

Polyphaser also suggests that a DC short in the radio is inadequate:
<http://www.polyphaser.com/cms_spol_app/techdocs/Built-in%20Coax.pdf>

>Any thoughts would be appreciated.
>
>Also want to ask: what about voltage surges of a few hundred volts or so
>induced on an antenna lead from a nearby lightning strike perhaps
>.
>The levels way below what would trip a gas tube I would imagine, but still
>more than enough to ruin a front end of a receiver.

A high value resistor should bleed off any charges. As others have suggested, a neon lamp and/or back to back diodes, should also work.

And I expect you're aware there's a thriving market in second-hand books via
companies such as Alibris, e.g.
http://www.alibris.com/booksearch?binding=&mtype=&keyword=antennas+for+all+applications.
That way you can gather what you need for much less money. I have purchased
books this way, stamped by parts of the US military, that are in fine
condition.

In another thread I've mentioned recently that the library of the IET
(formerly the IEE) in Savoy Place, London, is open to members of the public
free of charge to read all they have there, which is an impressive quantity
of material from throughout much of the history of radio. I daresay there
are equivalents in other countries.

Actually, I was not aware. If I needed a (used) book, I just ordered
it via Amazon. I haven't bought any paper books in several years
(bookshelf is full).

>http://www.alibris.com/booksearch?binding=&mtype=&keyword=antennas+for+all+applications.

I wish you hadn't done that. I just ordered a copy of Kraus (2nd
edition) for $25 and a 2nd copy of the ARRL Antenna Book for $19
(because it always seems to be out on loan). Sigh. I need to
practice resisting temptation. Internet shopping is far too easy.

Are you allowed to operate a 500 watt transmitter in the medium wave band in your country for student radio? That sounds a lot of power to cover a campus.

What is a 51/16 antenna? ... is that 3.19 wavelengths long? ... if so, that would be inefficient as a medium wave radiator.

You'll find that a pi network, as you propose, can be made to match almost anything to anything at a spot frequency, as long as the L and Cs have sufficient range, but you might have difficulty achieving adequate uniformity over the nominal 9 kHz bandwidth of a normal medium-wave transmission (i.e. a broadcast service).

Hah, be glad you don't live close to Powell's, which has a separate technical bookstore. My wallet is always a lot thinner when I walk out of there than when I walked in.

Many years ago, I used to make the pilgrimage to the Sunnyvale Fry's,
Ham Radio Outlet, various nearby surplus stores, and then Computer
Literacy Bookstore. After spending far too much money on books, I
started to avoid the bookstore. They solved the problem for me by
moving locations and finally closing in 2001.

A visit to San Francisco was not complete without dropping into
Stacey's bookstore on Market and Powell (after the one in Palo Alto
closed). However, the SF store closed earlier this year.
<http://www.sfgate.com/cgi-bin/article.cgi?f=/c/a/2009/01/07/BAFN154UV2.DTL>

What's left are the big chains, online vendors, and some specialty
stores. I've never been to Portland, but if I find an excuse, I'll
certainly give Powell's a visit.

Sorry about Stacey's. Always visited Stacey's when I would visit SF. I
liked Stacey's for code and hands-on books.

At this point, my national favorite technical bookstores are MIT Press
and the MIT Coop bookstore which are across the street from each other
at the Kendall stop of the Red Line in Cambridge, Mass.

Things aren't what they used to be: The 'Quantum' on technical books is
now $100 +/-, so I think twice before buying.

How much new is there in HF; VHF and UHF antennas anyway?

If it is new; it's not going to be in a book but rather in a journal like the IEEE Antenna and Propagation.

Most of the articles in Antennas and Propagation are mathematical and don't reduce easily to hardware implementations unless one has the inclination; time and an available machine shop.

I tend to buy used from amazon.com but generally if I know in advance what I want. Their "What's Inside" can be helpful though.

I have a couple of favorite antenna books and go to those when in need but generally rely on the basic equations relating wavelength and frequency and then cut-and-try.

Go on Mousers web site and look at gas tubes made by Littelfuse. Go to Littelfuses web site from the link on Mousers site and check out the specs on gas tubes. Compare them to the specs on your $50-70 commercial lightning arrestor.
Then note that what's in that little casting box is two coax connectors, one capacitor and one $2-3 gas tube and you have the answer to your question. Myth revealed.

I charge $75/hr for my work. If a $100 book will generate 1.33 hrs of billable labor, or save me about 3 hours in wasted time, it's break even. Anything over that is profitable. The only problem is that I'm not a professional antenna designer and don't generate much revenue from antenna projects. Still it's a good way to justify splurging on books. Incidentally, I make sure I have a least one consulting job per year so that I can justify deducting the book costs on my taxes.

>How much new is there in HF; VHF and UHF antennas anyway?

Ummm.... UWB, Fractal Antennas, MIMO, direction finding, disguise antennas, telematics antennas, sectored systems (WiMax), etc. It may not be new to those in the industry, but they're new to me. Instead of looking at what's new in antennas, look at what problems need to be solved that involve antennas. Low visual impact, cram multiple interfering radios inside a cell phone, limited tower space (combiners), 4x4 MIMO in a USB dongle?, etc.

>If it is new; it's not going to be in a book but rather in a journal

True, but the math offers a great clue on how they work. At this time, an IEEE membership, plus Ant and Prop subscription will burn about $200/year. I covered the costs in a previous rant at:
<http://groups.google.com/group/rec.radio.amateur.antenna/msg/ba3e3273c2f1b5d6>
I'm still trying to find a cheaper alternative buy joining the friends of the local university library.

>I tend to buy used from amazon.com but generally if I know in advance

Yep. Also Google Books.

Try antenna modeling with any of an assortment of programs.
<http://www.dxzone.com/catalog/Software/Antenna_analysis/>
Cut and try works ok for low frequency antennas, where large errors
are easily tolerated. Don't try that at microwave frequencies, where
the tweaks are in fractions of a millimeter.

I once suffered a severe case of lack of equilibrium, probably related to an adolescent experiment with ethanol containing liquids. It left a lasting impression on me and I avoid the state with great prejudice.

But since I have regained my equilibrium, my friends say that I am positively radiant! Perhaps our friend speaks sooth?

2460. Open wire feedline

Newsgroup: rec.radio.amateur.antenna
Date: 2009-09-28 18:44:45 UTC
From: Ron Walters <w4lde@numail.org>
Message-ID: <4ac103d3$0$11071$4c5efa9e@news.corp.moreusenet.net>
Source record: 12722

I am feeding a 80 meter center feed with open wire, about 100ft feed-line.

Due to some new construction work that is going to start on the back of our home this week I am forced to move the feed-line.

The original installation had about 50 ft vertical from the center of the dipole and then across and under a raised wood porch and then up to a second floor shack.

The porch is going and a new covered screened porch is replacing it.

I have three choices during construction, they are:

1. Leave the 100' feed-line coiled out in the yard and not operate. (Not a great idea)

2. Cut the feed line down to around 50' which would be temporary but then I would have to splice it later after construction.

3. Coil about 40' near the 4:1 balun, however I am concerned that the coiled feed line will act a one big inductor and change and or significantly reduce the antenna efficiency.

#3 is the easiest but I am worried about open wire feed-line coiled, thoughts please!

Adjacent coils of parallel feedline should never be located
very close to each other. The minimum spacing should be a
few times the spacing between the wires.

What I do is use a dacron messenger line. For instance, if
a knot is tied in the dacron messenger line every two feet
and at each knot, the length of the parallel line is four
feet, a transmission spiral will result where 100 feet of
ladder-line can be spiraled into 50 linear feet of messenger
line. The ladder-line can be attached at the knots using
black nylon tie wraps. Hope this is understandable and helps.

If you coil the transmission line so that the distance between turns is much greater than the distance between the conductors, you will not significantly alter its differential mode operation (which is its main purpose in most antenna systems).

You will alter the common mode current distribution, probably for the better. Remember that some folk use common mode chokes in systems using open wire feeder, and you will create a common mode choke by coiling the line as I described.

You could suspend the coil on a roughly horizontal span of nylon fishing line to support and space the turns.

I have been looking for a decent CP design to try out on my
repeaters .
For many years I have been looking at the reasoning for FM
broadcasters having used CP pol with great success.

I also have a small indication that linear antennas (eg:linear
collinears)and non-linear antennas(eg:folded loop dipoles) by design
may have slightly different characteristics in the far field that
tend towards a greater degree of cross/CP from the mechanical design .

Anyone had good success with installing a CP repeater antenna(2m or
70cm) to assist with the deap fade nulls in mobile uplink to the
repeater.
I want to try rhp for TX and lhp for RX - anyone tried this
combination before?

In the UK, Band II VHF FM sound radio broadcasting began to fixed receivers using horizontal polarisation (HP) for reasons including a belief that interference from car ignition systems was predominantly vertically polarised, and because it was found easier to achieve a good omni-directional pattern in the horizontal plane from a transmitting antenna based on a vertical slot (Babinet's principle) - several such slot antennas were stacked vertically to obtain some gain and to avoid illuminating the sky.

Later, as transistors became available and vehicular VHF receivers of sensible size became practical, a new market emerged but it was poorly served by the HP transmissions*. When local radio was launched in the UK, in Band II, the new transmitters were equipped with antennas that radiated a VP component as well as HP, and in time all Band II transmissions were converted to mixed polarisation. Circular polarisation is one example of mixed polarisation, but its ability to provide cross-polar discrimination is not used in FM broadcasting.

Take a look at: http://downloads.bbc.co.uk/rd/pubs/reports/1970-35.pdf

The experience in other countries has probably been similar - same physics.

Huh?

* HP is less effective than VP for VHF communication with mobiles because the ever-present ground reflection has reversed polarity (i.e. it's in antiphase with the signal propagating over a direct path).

> Anyone had good success with installing a CP repeater antenna(2m or
> 70cm) to assist with the deap fade nulls in mobile uplink to the

If you use the same antenna for transmitting and receiving, and it is fundamentally circularly polarised, then it will provide and respond to the two different senses of CP automatically because the definition of the sense of circular polarisation depends on the direction of propagation. But do you think the horizontally-polarised component will help with deep nulls?

Chris

Reflection of a CP wave results in a reversed CP wave only when the reflection is directly normal to the reflecting surface. That's not at all the case for typical ground reflections. What you actually get from ground reflections is an elliptically polarized wave, likely having the same sense as the impinging wave. In experiments I ran about 35 years ago, I found nearly linearly polarized waves resulting from reflection of a CP wave from a vehicle top.

A little time spent with a modeling program such as EZNEC+ can be very educational in understanding the generation and reflection of CP waves.

Methinks you'll be better off with eliptical polarization, where
perhaps 70% of the power is vertically polarized, and the rest is
horizontal. The idea is that most of the energy will be properly
recieved by the traditional vertically polarized mobile antenna. The
remainder will be to fill in the gaps, where the polarization changes
to something not so vertical.

Search Google patents:
<http://www.google.com/patents>
for "omnidirectional circular polarized antenna". Also, look at FM
broadcast xmit antennas. Some really strange stuff there.

>Anyone had good success with installing a CP repeater antenna(2m or
>70cm) to assist with the deap fade nulls in mobile uplink to the
>repeater.

Yes. I can't find my previous rant on the subject, so I'll try again.
Around 1968 thru 1970, I was at Cal Poly Pomona doing some experiments
with CP UHF antennas. The problem was that the local repeater was
experiencing deep Raleigh fading as mobiles moved along the San
Bernardino Freeway. The ideas was that CP would reduce these fades so
that listening to the repeater didn't sound like it was accompanied by
a machine gun. It worked but with a price. The fades were
dramatically reduced, but so was the coverage area. Antenna gain was
down at least 3dB as was maximum range for the repeater. I thought it
was a good tradeoff, but not everyone agreed. The stations that were
marginal (usually because they were too lazy to install a proper
antenna) were gone. However, the reliability of the local mobiles was
greatly improved. Range won over fade reduction and the antenna was
replaced after a few months of testing.

There was an article on the subject in "The Practical Handbook of
Amateur Radio FM and Repeaters" by Bill Pasternack and Mike Morris.
1981 by Tab Books.

<http://openlibrary.org/b/OL4421123M/practical_handbook_of_amateur_radio_FM___repeaters>
<http://www.alibris.com/booksearch?qsort=p&isbn=0830612122>
Sheesh. I paid about $5 at a hamfest.

Since it's not online, I scanned the applicable chapter, chopped out
some irrelevant junk, and posted them to:
<http://802.11junk.com/jeffl/circular-polarization/>
I'll convert them to a single PDF after I figure out why Irfanview is
generating garbage. Bug me if you have trouble reading the JPG's.

>I want to try rhp for TX and lhp for RX - anyone tried this
>combination before?

Yep. I tried that to improve TX-RX isolation. I gave up. Mounted on
a single pole, with separate phasing harnesses, I never could get the
antennas anywhere near 50 ohms. There was also just too much coupling
between the RH and LH sections for that to work. Another explanation
might be that at the time, I didn't have a clue what I was doing, but
we won't go there. The rather high VSWR certainly didn't help with
the isolation as it detuned the tx and rx cavities (formerly a
duplexer). Some rather crude testing showed that we were better off
with a single antenna, the stock duplexer, and a single CP
polarization. There was also a problem with distant stations. They
wanted to use CP on the base station to reduce the effects of
multipath (usually off the infamous L.A. smog inversion layer). That
would have required two antennas for each base station. I suggest
that you stick with one circular polarization for now.

Incidentally, note the scanned photo of the Loop Mountain site
<http://802.11junk.com/jeffl/circular-polarization/cp-02.jpg>
and compare it with the previous intermod factory and post-storm
removal exercise at:
<http://802.11junk.com/jeffl/pics/Old%20Repeaters/slides/LoopMtn02.html>
<http://802.11junk.com/jeffl/pics/Old%20Repeaters/slides/LoopMtn03.html>
One of the reasons I'm current intact and still sane is that I don't
own any repeaters and find excuses not to do any tower work.

The most comprehensive treatise on antennas, IMHO, is "Antenna Theory",
Parts I & II, by Collin and Zucker, McGraw-Hill. This two-book set is not
really intended for the hobbyist, however. The other great antenna books
in my office bookcase:

1. J.D. Kraus, "Antennas", McGraw-Hill

2. H. Jasik, "Antenna Engineering Handbook", MxGraw-Hill

3. E. Jordan & H. Balmain, "Electromagnetic Waves and Radiating Systems",
Prentice-Hall

4. R.W.P. King & C. Harrison, "Antennas and Waves: A Modern Approach",
The M.I.T. Press

5. W. L. Weeks, "Antenna Engineering", McGraw-Hill

6. S. Schelkunoff & H.T. Friis, "Antennas Theory and Practice", J. W.
Wiley & Sons

7. V. Rumsey, "Frequency Independent Antennas", Academic Press

8. P.E. Law Jr., "Shipboard Antennas", Artech House (this book deals with
antennas used by the USN)

9. Various ARRL handbooks and compendia on antennas.

Many of these references go back a number of decades and I don't know if
they're still in print. Sincerely, and 73s from N4GGO,

No doubt, but what I wrote above was about horizontal and vertical _linear_
polarisations, HP and VP. I did wonder after I sent it if 'polarity' would
be misread as polarisation.

Wind 4 or 5 turns around an empty plastic water butt, and keep the
turns well separated. Like Owen said, it'll also serve as a nice
common-mode choke!

Hello,

Do you mean 16m vertical and 51m horizontal or 51m total with 16m
vertical? How big is the coverage area?

For ease of matching it is best to have a quarter wavelength (so about
51m totally). To get reasonable antenna efficiency and safe operation,
you need a ground network. For best efficiency and local coverage,
you need a large vertical part.

Without some form of grounding you will get sufficient RF voltage on
your cable (and maybe transmitter installation) that may result in
(skin)burn and other (EMC) problems.

Best way ahead is first design the antenna with ground system (local
coverage assumed). Then you can measure the impedance and maybe change
the antenna setup to get reasonable impedance. After that you can
design the matching network en select the components.

You are right; VSWR meter is between transmitter and antenna matching
unit. When you are unfamiliar with antennas and RF power, I would
recommend you to visit a local radio amateur club for advise, as with
500W AM many things can (and will) go wrong. Did you also check the
legal aspects?

Best regards,
Wim

#3 is less than optimal unless you actually want a big coiled piece of feedline as part of your antenna setup. There are some folks that have big coils of feedline just for impedance transformation purposes, I always think it's odd but that's what they like.

Splicing parallel feedline (whether it be homebrew ladder line or commercial window line) is not a big deal. The copper plated steel stuff is hard to bend with your bare hands but is easy enough with pliers. Splicing it with solder, and without a good mechanical twisted splice, will mean that after some flexing it will be break at the splice point. But make a good mechanical splice like in the handbook and you'll do fine.

But if you don't really need that 50 feet of feedline then why keep it? Straightest shot to the antenna will always be superior unless you want that extra 50 feet for impedance transformation or something else. Sounds like in most circumstances it'll be a win-win to keep the shorter more direct routing.

Tim.

100 feet of ladder-line with an 80m dipole is easy to understand.
The dipole is 1/2WL. The ladder-line is ~1/2WL. The low 80m
feedpoint impedance tends to be reproduced at the shack end
thus making for an easy match.

However, 50 feet of ladder-line is ~1/4WL. The low 80m feedpoint
impedance tends to be transformed to ~4k ohms. Most built-in
autotuners will not handle such impedances.

100 feet of ladder-line is also a good length for multiband
operation of an 80m dipole as can be seen from this chart:

http://www.w5dxp.com/pnts130.gif

50 feet of ladder-line seems to be a good length for HF amateur
frequencies above 10 MHz - not so good for 80m and 40m.
